User's Guide

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

About This Manual

This manual discusses modules and peripherals of the MSP430x2xx family of devices. Each discussion presents the module or peripheral in a general sense. Not all features and functions of all modules or peripherals are present on all devices. In addition, modules or peripherals may differ in their exact implementation between device families, or may not be fully implemented on an individual device or device family.

Pin functions, internal signal connections, and operational parameters differ from device to device. The user should consult the device-specific datasheet for these details.

Related Documentation From Texas Instruments

For related documentation see the web site <http://www.ti.com/msp430>.

FCC Warning

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

Notational Conventions

Program examples, are shown in a special typeface.

Glossary

ACLK	Auxiliary Clock	See <i>Basic Clock Module</i>
ADC	Analog-to-Digital Converter	
BOR	Brown-Out Reset	See <i>System Resets, Interrupts, and Operating Modes</i>
BSL	Bootstrap Loader	See www.ti.com/msp430 for application reports
CPU	Central Processing Unit	See <i>RISC 16-Bit CPU</i>
DAC	Digital-to-Analog Converter	
DCO	Digitally Controlled Oscillator	See <i>Basic Clock Module</i>
dst	Destination	See <i>RISC 16-Bit CPU</i>
FLL	Frequency Locked Loop	See <i>FLL+</i> in MSP430x4xx Family User's Guide
GIE	General Interrupt Enable	See <i>System Resets Interrupts and Operating Modes</i>
INT(N/2)	Integer portion of N/2	
I/O	Input/Output	See <i>Digital I/O</i>
ISR	Interrupt Service Routine	
LSB	Least-Significant Bit	
LSD	Least-Significant Digit	
LPM	Low-Power Mode	See <i>System Resets Interrupts and Operating Modes</i>
MAB	Memory Address Bus	
MCLK	Master Clock	See <i>Basic Clock Module</i>
MDB	Memory Data Bus	
MSB	Most-Significant Bit	
MSD	Most-Significant Digit	
NMI	(Non)-Maskable Interrupt	See <i>System Resets Interrupts and Operating Modes</i>
PC	Program Counter	See <i>RISC 16-Bit CPU</i>
POR	Power-On Reset	See <i>System Resets Interrupts and Operating Modes</i>
PUC	Power-Up Clear	See <i>System Resets Interrupts and Operating Modes</i>
RAM	Random Access Memory	
SCG	System Clock Generator	See <i>System Resets Interrupts and Operating Modes</i>
SFR	Special Function Register	
SMCLK	Sub-System Master Clock	See <i>Basic Clock Module</i>
SP	Stack Pointer	See <i>RISC 16-Bit CPU</i>
SR	Status Register	See <i>RISC 16-Bit CPU</i>
src	Source	See <i>RISC 16-Bit CPU</i>
TOS	Top-of-Stack	See <i>RISC 16-Bit CPU</i>
WDT	Watchdog Timer	See <i>Watchdog Timer</i>

Register Bit Conventions

Each register is shown with a key indicating the accessibility of the each individual bit, and the initial condition:

Register Bit Accessibility and Initial Condition

Key	Bit Accessibility
rw	Read/write
r	Read only
r0	Read as 0
r1	Read as 1
w	Write only
w0	Write as 0
w1	Write as 1
(w)	No register bit implemented; writing a 1 results in a pulse. The register bit is always read as 0.
h0	Cleared by hardware
h1	Set by hardware
-0,-1	Condition after PUC
-(0),-(1)	Condition after POR

Introduction

This chapter describes the architecture of the MSP430.

Topic	Page
1.1 Architecture	1-2
1.2 Flexible Clock System	1-2
1.3 Embedded Emulation	1-3
1.4 Address Space	1-4
1.5 MSP430x2xx Family Enhancements	1-6

1.1 Architecture

The MSP430 incorporates a 16-bit RISC CPU, peripherals, and a flexible clock system that interconnect using a von-Neumann common memory address bus (MAB) and memory data bus (MDB). Partnering a modern CPU with modular memory-mapped analog and digital peripherals, the MSP430 offers solutions for demanding mixed-signal applications.

Key features of the MSP430x2xx family include:

- ☐ Ultralow-power architecture extends battery life
 - 0.1- μ A RAM retention
 - 0.8- μ A real-time clock mode
 - 250- μ A / MIPS active
- ☐ High-performance analog ideal for precision measurement
 - Comparator-gated timers for measuring resistive elements
- ☐ 16-bit RISC CPU enables new applications at a fraction of the code size.
 - Large register file eliminates working file bottleneck
 - Compact core design reduces power consumption and cost
 - Optimized for modern high-level programming
 - Only 27 core instructions and seven addressing modes
 - Extensive vectored-interrupt capability
- ☐ In-system programmable Flash permits flexible code changes, field upgrades and data logging

1.2 Flexible Clock System

The clock system is designed specifically for battery-powered applications. A low-frequency auxiliary clock (ACLK) is driven directly from a common 32-kHz watch crystal. The ACLK can be used for a background real-time clock self wake-up function. An integrated high-speed digitally controlled oscillator (DCO) can source the master clock (MCLK) used by the CPU and high-speed peripherals. By design, the DCO is active and stable in less than 2 μ s @ 1 Mhz. MSP430-based solutions effectively use the high-performance 16-bit RISC CPU in very short bursts.

- ☐ Low-frequency auxiliary clock = Ultralow-power stand-by mode
- ☐ High-speed master clock = High performance signal processing

Figure 1–1. MSP430 Architecture

1.3 Embedded Emulation

Dedicated embedded emulation logic resides on the device itself and is accessed via JTAG using no additional system resources.

The benefits of embedded emulation include:

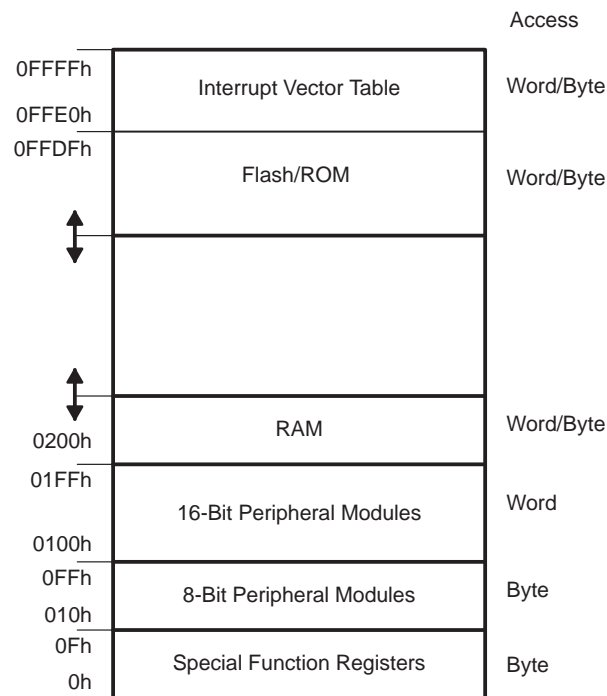

- ☐ Unobtrusive development and debug with full-speed execution, breakpoints, and single-steps in an application are supported.
- ☐ Development is in-system subject to the same characteristics as the final application.
- ☐ Mixed-signal integrity is preserved and not subject to cabling interference.

1.4 Address Space

The MSP430 von-Neumann architecture has one address space shared with special function registers (SFRs), peripherals, RAM, and Flash/ROM memory as shown in Figure 1–2. See the device-specific data sheets for specific memory maps. Code access are always performed on even addresses. Data can be accessed as bytes or words.

The addressable memory space is 64 KB with future expansion planned.

Figure 1–2. Memory Map

1.4.1 Flash/ROM

The start address of Flash/ROM depends on the amount of Flash/ROM present and varies by device. The end address for Flash/ROM is 0FFFFh. Flash can be used for both code and data. Word or byte tables can be stored and used in Flash/ROM without the need to copy the tables to RAM before using them.

The interrupt vector table is mapped into the upper 16 words of Flash/ROM address space, with the highest priority interrupt vector at the highest Flash/ROM word address (0FFFEh).

1.4.2 RAM

RAM starts at 0200h. The end address of RAM depends on the amount of RAM present and varies by device. RAM can be used for both code and data.

1.4.3 Peripheral Modules

Peripheral modules are mapped into the address space. The address space from 0100 to 01FFh is reserved for 16-bit peripheral modules. These modules should be accessed with word instructions. If byte instructions are used, only even addresses are permissible, and the high byte of the result is always 0.

The address space from 010h to 0FFh is reserved for 8-bit peripheral modules. These modules should be accessed with byte instructions. Read access of byte modules using word instructions results in unpredictable data in the high byte. If word data is written to a byte module only the low byte is written into the peripheral register, ignoring the high byte.

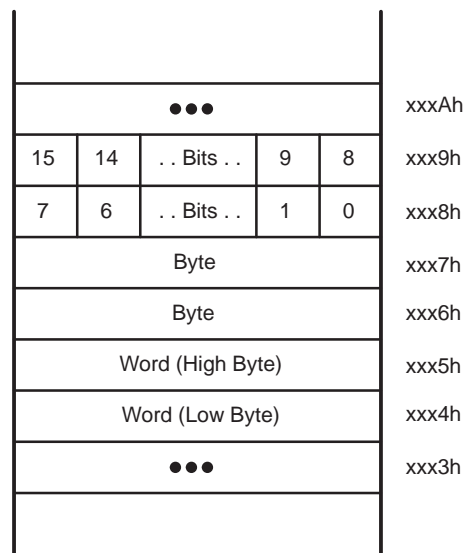

1.4.4 Special Function Registers (SFRs)

Some peripheral functions are configured in the SFRs. The SFRs are located in the lower 16 bytes of the address space, and are organized by byte. SFRs must be accessed using byte instructions only. See the device-specific data sheets for applicable SFR bits.

1.4.5 Memory Organization

Bytes are located at even or odd addresses. Words are only located at even addresses as shown in Figure 1–3. When using word instructions, only even addresses may be used. The low byte of a word is always an even address. The high byte is at the next odd address. For example, if a data word is located at address xxx4h, then the low byte of that data word is located at address xxx4h, and the high byte of that word is located at address xxx5h.

Figure 1–3. Bits, Bytes, and Words in a Byte-Organized Memory

1.5 MSP430x2xx Family Enhancements

Table 1–1 highlights enhancements made to the MSP430x2xx family. The enhancements are discussed fully in the following chapters, or in the case of improved device parameters, shown in the device-specific datasheet.

Table 1–1. MSP430x2xx Family Enhancements

Subject	Enhancement
Reset	<ul style="list-style-type: none"> – Brownout reset is included on all MSP430x2xx devices. – PORIFG and RSTIFG flags have been added to IFG1 to indicate the cause of a reset. – An instruction fetch from the address range 0x0000 – 0x01FF will reset the device.
Watchdog Timer	<ul style="list-style-type: none"> – All MSP430x2xx devices integrate the Watchdog Timer+ module (WDT+). The WDT+ ensures the clock source for the timer is never disabled.
Basic Clock System	<ul style="list-style-type: none"> – The LFXT1 oscillator has selectable load capacitors in LF mode. – The LFXT1 supports up to 16-MHz crystals in HF mode. – The LFXT1 includes oscillator fault detection in LF mode. – The XIN and XOUT pins are shared function pins on 20- and 28-pin devices. – The external R_{OSC} feature of the DCO not supported on some devices. Software should not set the LSB of the BCSCTL2 register in this case. See the device-specific datasheet for details. – The DCO operating frequency has been significantly increased. – The DCO temperature stability has been significantly improved.
Flash Memory	<ul style="list-style-type: none"> – The information memory has 4 segments of 64-Bytes each. – SegmentA is individually locked with the LOCKA bit. – All information is protected from mass erase with the LOCKA bit. – Segment erases can be interrupted by an interrupt. – Flash updates can be aborted by an interrupt. – Flash programming voltage has been lowered to 2.2 V – Program/erase time has been reduced. – Clock failure aborts a flash update.
Digital I/O	<ul style="list-style-type: none"> – Ports 1 and 2 have integrated pull-up/down resistors. – P2.6 and P2.7 functions have been added to 20- and 28- pin devices. These are shared functions with XIN and XOUT. Software must not clear the P2SELx bits for these pins if crystal operation is required.
Comparator_A	<ul style="list-style-type: none"> – Comparator_A has expanded input capability with a new input multiplexer.
Low Power	<ul style="list-style-type: none"> – Typical LPM3 current consumption has been reduced almost 50% @3V. – DCO startup time has been significantly reduced.
Operating frequency	<ul style="list-style-type: none"> – The target maximum operating frequency is 16Mhz @ 3.3V.
BSL	<ul style="list-style-type: none"> – An incorrect password causes a mass erase. – BSL entry sequence is more robust to prevent accidental entry and erasure.

System Resets, Interrupts, and Operating Modes

This chapter describes the MSP430x2xx system resets, interrupts, and operating modes.

Topic	Page
2.1 System Reset and Initialization	2-2
2.2 Interrupts	2-5
2.3 Operating Modes	2-14
2.4 Principles for Low-Power Applications	2-17
2.5 Connection of Unused Pins	2-17

Figure 2–1. Power-On Reset and Power-Up Clear Schematic

- ☐ A POR signal
- ☐ Watchdog timer expiration when in watchdog mode only
- ☐ Watchdog timer security key violation
- ☐ A Flash memory security key violation
- ☐ A CPU instruction fetch from the peripheral address range 0h – 01FFh

2.1.1 Brownout Reset (BOR)

The brownout reset circuit detects low supply voltages such as when a supply voltage is applied to or removed from the V_{CC} terminal. The brownout reset circuit resets the device by triggering a POR signal when power is applied or removed. The operating levels are shown in Figure 2–2.

The POR signal becomes active when V_{CC} crosses the $V_{CC(start)}$ level. It remains active until V_{CC} crosses the $V_{(B_IT+)}$ threshold and the delay $t_{(BOR)}$ elapses. The delay $t_{(BOR)}$ is adaptive being longer for a slow ramping V_{CC} . The hysteresis $V_{hys(B_IT-)}$ ensures that the supply voltage must drop below $V_{(B_IT-)}$ to generate another POR signal from the brownout reset circuitry.

Figure 2–2. Brownout Timing

As the $V_{(B_IT-)}$ level is significantly above the V_{min} level of the POR circuit, the BOR provides a reset for power failures where V_{CC} does not fall below V_{min} . See device-specific datasheet for parameters.

2.1.2 Device Initial Conditions After System Reset

After a POR, the initial MSP430 conditions are:

- ☐ The $\overline{\text{RST}}$ /NMI pin is configured in the reset mode.
- ☐ I/O pins are switched to input mode as described in the *Digital I/O* chapter.
- ☐ Other peripheral modules and registers are initialized as described in their respective chapters in this manual.
- ☐ Status register (SR) is reset.
- ☐ The watchdog timer powers up active in watchdog mode.
- ☐ Program counter (PC) is loaded with address contained at reset vector location (0FFFEh). If the reset vectors content is 0FFFFh the device will be disabled for minimum power consumption.

Software Initialization

After a system reset, user software must initialize the MSP430 for the application requirements. The following must occur:

- ☐ Initialize the SP, typically to the top of RAM.
- ☐ Initialize the watchdog to the requirements of the application.
- ☐ Configure peripheral modules to the requirements of the application.

Additionally, the watchdog timer, oscillator fault, and flash memory flags can be evaluated to determine the source of the reset.

2.2 Interrupts

The interrupt priorities are fixed and defined by the arrangement of the modules in the connection chain as shown in Figure 2–3. The nearer a module is to the CPU/NMIRS, the higher the priority. Interrupt priorities determine what interrupt is taken when more than one interrupt is pending simultaneously.

There are three types of interrupts:

- ☐ System reset
- ☐ (Non)-maskable NMI
- ☐ Maskable

Figure 2–3. Interrupt Priority

2.2.1 (Non)-Maskable Interrupts (NMI)

(Non)-maskable NMI interrupts are not masked by the general interrupt enable bit (GIE), but are enabled by individual interrupt enable bits (NMIIE, ACCVIE, OFIE). When a NMI interrupt is accepted, all NMI interrupt enable bits are automatically reset. Program execution begins at the address stored in the (non)-maskable interrupt vector, 0FFFCh. User software must set the required NMI interrupt enable bits for the interrupt to be re-enabled. The block diagram for NMI sources is shown in Figure 2–4.

A (non)-maskable NMI interrupt can be generated by three sources:

- ☐ An edge on the $\overline{\text{RST}}/\text{NMI}$ pin when configured in NMI mode
- ☐ An oscillator fault occurs
- ☐ An access violation to the flash memory

Reset/NMI Pin

At power-up, the $\overline{\text{RST}}/\text{NMI}$ pin is configured in the reset mode. The function of the $\overline{\text{RST}}/\text{NMI}$ pins is selected in the watchdog control register WDTCTL. If the $\overline{\text{RST}}/\text{NMI}$ pin is set to the reset function, the CPU is held in the reset state as long as the $\overline{\text{RST}}/\text{NMI}$ pin is held low. After the input changes to a high state, the CPU starts program execution at the word address stored in the reset vector, 0FFFEh, and the RSTIFG flag is set.

If the $\overline{\text{RST}}/\text{NMI}$ pin is configured by user software to the NMI function, a signal edge selected by the WDTNMIES bit generates an NMI interrupt if the NMIIE bit is set. The $\overline{\text{RST}}/\text{NMI}$ flag NMIFG is also set.

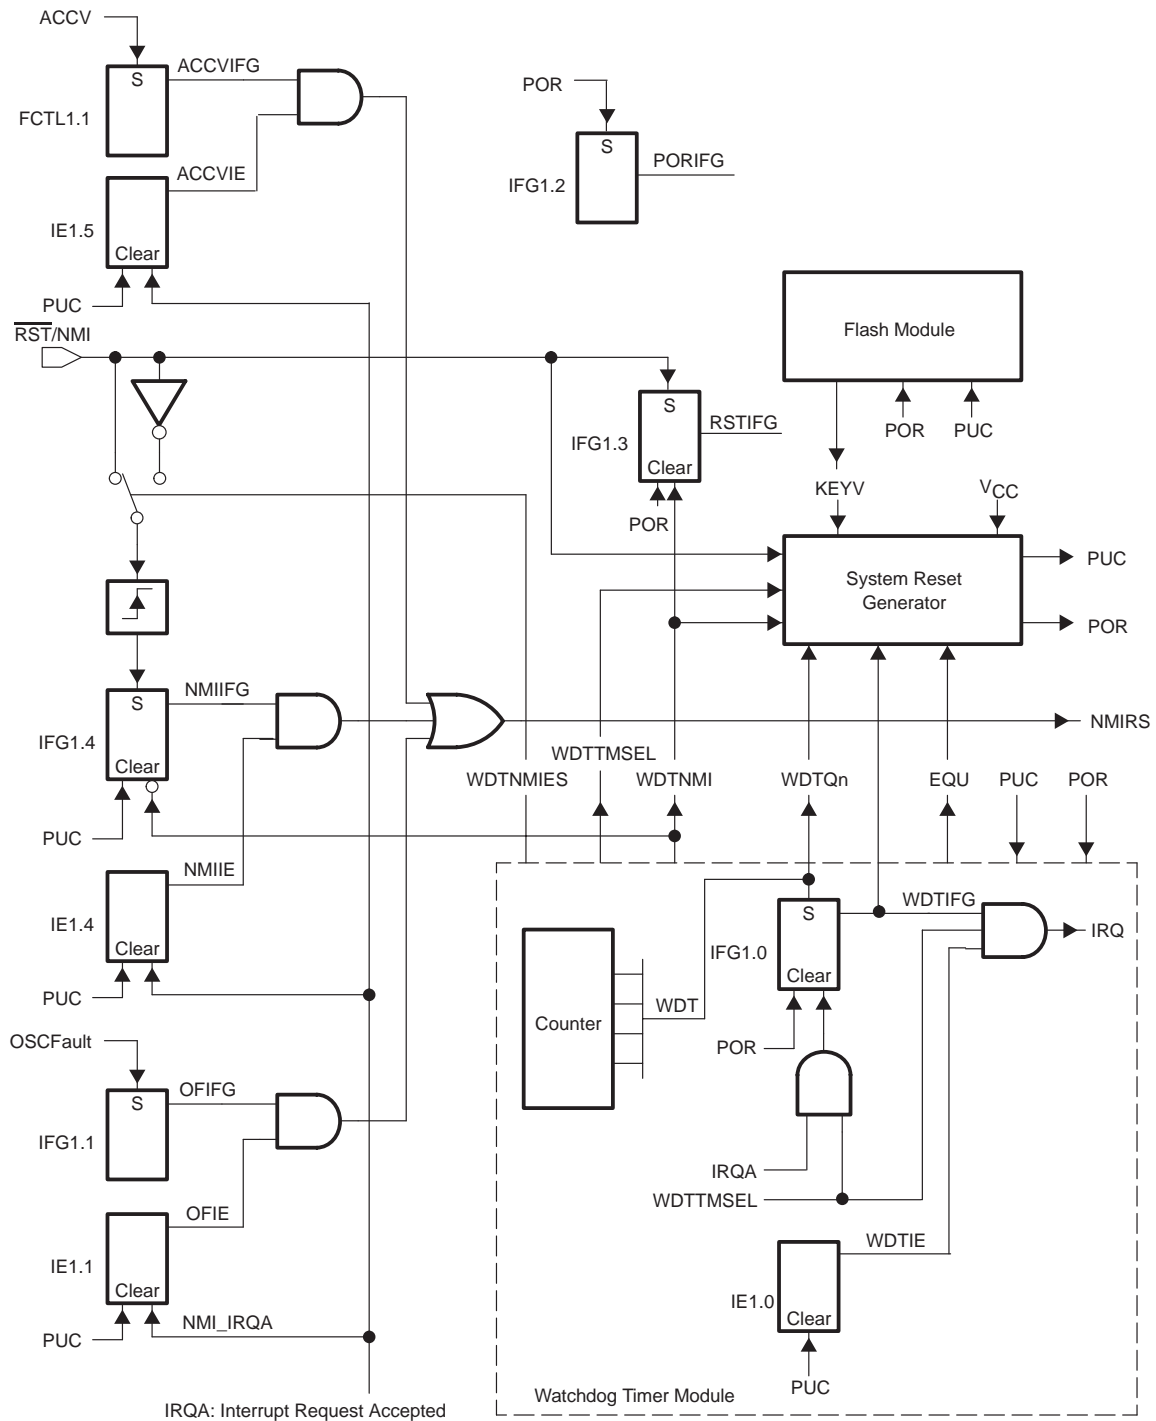

Note: Holding $\overline{\text{RST}}/\text{NMI}$ Low

When configured in the NMI mode, a signal generating an NMI event should not hold the $\overline{\text{RST}}/\text{NMI}$ pin low. If a PUC occurs from a different source while the NMI signal is low, the device will be held in the reset state because a PUC changes the $\overline{\text{RST}}/\text{NMI}$ pin to the reset function.

Note: Modifying WDTNMIES

When NMI mode is selected and the WDTNMIES bit is changed, an NMI can be generated, depending on the actual level at the $\overline{\text{RST}}/\text{NMI}$ pin. When the NMI edge select bit is changed before selecting the NMI mode, no NMI is generated.

Figure 2–4. Block Diagram of (Non)-Maskable Interrupt Sources

Flash Access Violation

The flash ACCVIFG flag is set when a flash access violation occurs. The flash access violation can be enabled to generate an NMI interrupt by setting the ACCVIE bit. The ACCVIFG flag can then be tested by NMI the interrupt service routine to determine if the NMI was caused by a flash access violation.

Oscillator Fault

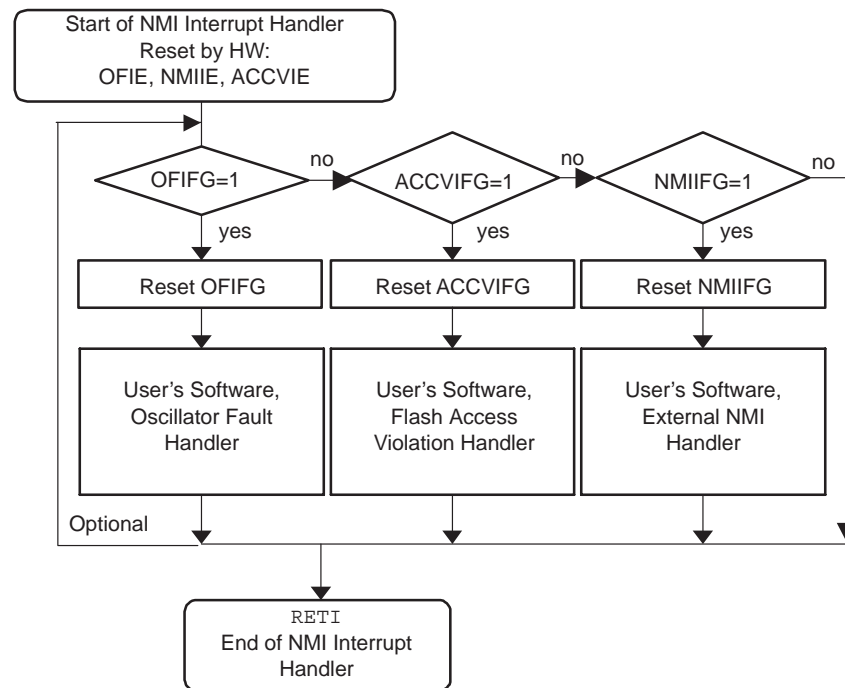

The oscillator fault signal warns of a possible error condition with the crystal oscillator. The oscillator fault can be enabled to generate an NMI interrupt by setting the OFIE bit. The OFIFG flag can then be tested by NMI the interrupt service routine to determine if the NMI was caused by an oscillator fault.

A PUC signal can trigger an oscillator fault, because the PUC switches the LFXT1 to LF mode, therefore switching off the HF mode. The PUC signal also switches off the XT2 oscillator.

Example of an NMI Interrupt Handler

The NMI interrupt is a multiple-source interrupt. An NMI interrupt automatically resets the NMIIE, OFIE and ACCVIE interrupt-enable bits. The user NMI service routine resets the interrupt flags and re-enables the interrupt-enable bits according to the application needs as shown in Figure 2–5.

Figure 2–5. NMI Interrupt Handler

Note: Enabling NMI Interrupts with ACCVIE, NMIIE, and OFIE

To prevent nested NMI interrupts, the ACCVIE, NMIIE, and OFIE enable bits should not be set inside of an NMI interrupt service routine.

2.2.2 Maskable Interrupts

Maskable interrupts are caused by peripherals with interrupt capability including the watchdog timer overflow in interval-timer mode. Each maskable interrupt source can be disabled individually by an interrupt enable bit, or all maskable interrupts can be disabled by the general interrupt enable (GIE) bit in the status register (SR).

Each individual peripheral interrupt is discussed in the associated peripheral module chapter in this manual.

2.2.3 Interrupt Processing

When an interrupt is requested from a peripheral and the peripheral interrupt enable bit and GIE bit are set, the interrupt service routine is requested. Only the individual enable bit must be set for (non)-maskable interrupts to be requested.

Interrupt Acceptance

The interrupt latency is 6 cycles, starting with the acceptance of an interrupt request, and lasting until the start of execution of the first instruction of the interrupt-service routine, as shown in Figure 2–6. The interrupt logic executes the following:

- 1) Any currently executing instruction is completed.
- 2) The PC, which points to the next instruction, is pushed onto the stack.
- 3) The SR is pushed onto the stack.
- 4) The interrupt with the highest priority is selected if multiple interrupts occurred during the last instruction and are pending for service.
- 5) The interrupt request flag resets automatically on single-source flags. Multiple source flags remain set for servicing by software.
- 6) The SR is cleared. This terminates any low-power mode. Because the GIE bit is cleared, further interrupts are disabled.
- 7) The content of the interrupt vector is loaded into the PC: the program continues with the interrupt service routine at that address.

Figure 2–6. Interrupt Processing

Return From Interrupt

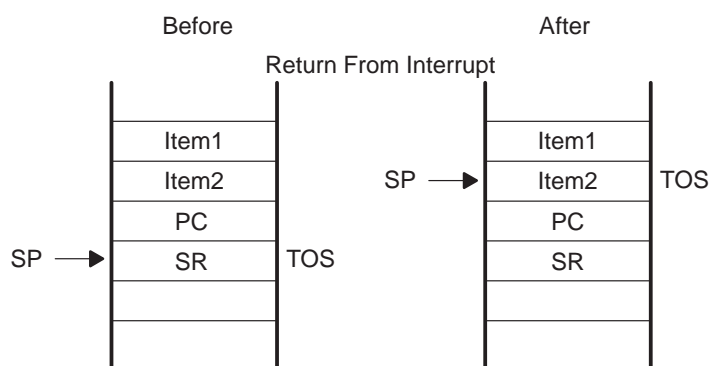

The interrupt handling routine terminates with the instruction:

`RETI` (return from an interrupt service routine)

The return from the interrupt takes 5 cycles to execute the following actions and is illustrated in Figure 2–7.

- 1) The SR with all previous settings pops from the stack. All previous settings of GIE, CPUOFF, etc. are now in effect, regardless of the settings used during the interrupt service routine.
- 2) The PC pops from the stack and begins execution at the point where it was interrupted.

Figure 2–7. Return From Interrupt

Interrupt Nesting

Interrupt nesting is enabled if the GIE bit is set inside an interrupt service routine. When interrupt nesting is enabled, any interrupt occurring during an interrupt service routine will interrupt the routine, regardless of the interrupt priorities.

2.2.4 Interrupt Vectors

The interrupt vectors and the power-up starting address are located in the address range 0FFFFh – 0FFC0h as described in Table 2–1. A vector is programmed by the user with the 16-bit address of the corresponding interrupt service routine. See the device-specific data sheet for the complete interrupt vector list.

It is recommended to provide an interrupt service routine for each interrupt vector that is assigned to a module. A dummy interrupt service routine can consist of just the RETI instruction and several interrupt vectors can point to it.

Unassigned interrupt vectors can be used for regular program code if necessary.

Some module enable bits, interrupt enable bits, and interrupt flags are located in the SFRs. The SFRs are located in the lower address range and are implemented in byte format. SFRs must be accessed using byte instructions. See the device-specific datasheet for the SFR configuration.

Table 2–1. Interrupt Sources, Flags, and Vectors

INTERRUPT SOURCE	INTERRUPT FLAG	SYSTEM INTERRUPT	WORD ADDRESS	PRIORITY
Power-up, external reset, watchdog, flash password, illegal instruction fetch	PORIFG RSTIFG WDTIFG KEYV	Reset	0FFFEh	31, highest
NMI, oscillator fault, flash memory access violation	NMIIFG OFIFG ACCVIFG	(non)-maskable (non)-maskable (non)-maskable	0FFFCCh	30

2.3 Operating Modes

The MSP430 family is designed for ultralow-power applications and uses different operating modes shown in Figure 2–9.

The operating modes take into account three different needs:

- ☐ Ultralow-power
- ☐ Speed and data throughput
- ☐ Minimization of individual peripheral current consumption

The MSP430 typical current consumption is shown in Figure 2–8.

Figure 2–8. Typical Current Consumption of 21x1 Devices vs Operating Modes

The low-power modes 0–4 are configured with the CPUOFF, OSCOFF, SCG0, and SCG1 bits in the status register. The advantage of including the CPUOFF, OSCOFF, SCG0, and SCG1 mode-control bits in the status register is that the present operating mode is saved onto the stack during an interrupt service routine. Program flow returns to the previous operating mode if the saved SR value is not altered during the interrupt service routine. Program flow can be returned to a different operating mode by manipulating the saved SR value on the stack inside of the interrupt service routine. The mode-control bits and the stack can be accessed with any instruction.

When setting any of the mode-control bits, the selected operating mode takes effect immediately. Peripherals operating with any disabled clock are disabled until the clock becomes active. The peripherals may also be disabled with their individual control register settings. All I/O port pins and RAM/registers are unchanged. Wake up is possible through all enabled interrupts.

Figure 2–9. MSP430x2xx Operating Modes For Basic Clock System

SCG1	SCG0	OSCOFF	CPUOFF	Mode	CPU and Clocks Status
0	0	0	0	Active	CPU is active, all enabled clocks are active
0	0	0	1	LPM0	CPU, MCLK are disabled SMCLK, ACLK are active
0	1	0	1	LPM1	CPU, MCLK, DCO osc. are disabled DC generator is disabled if the DCO is not used for MCLK or SMCLK in active mode SMCLK, ACLK are active
1	0	0	1	LPM2	CPU, MCLK, SMCLK, DCO osc. are disabled DC generator remains enabled ACLK is active
1	1	0	1	LPM3	CPU, MCLK, SMCLK, DCO osc. are disabled DC generator disabled ACLK is active
1	1	1	1	LPM4	CPU and all clocks disabled

2.3.1 Entering and Exiting Low-Power Modes

An enabled interrupt event wakes the MSP430 from any of the low-power operating modes. The program flow is:

- ❑ Enter interrupt service routine:
 - The PC and SR are stored on the stack
 - The CPUOFF, SCG1, and OSCOFF bits are automatically reset
- ❑ Options for returning from the interrupt service routine:
 - The original SR is popped from the stack, restoring the previous operating mode.
 - The SR bits stored on the stack can be modified within the interrupt service routine returning to a different operating mode when the RETI instruction is executed.

```
; Enter LPM0 Example
    BIS    #GIE+CPUOFF,SR          ; Enter LPM0
;    ...                          ; Program stops here
;
; Exit LPM0 Interrupt Service Routine
    BIC    #CPUOFF,0(SP)           ; Exit LPM0 on RETI
    RETI

; Enter LPM3 Example
    BIS    #GIE+CPUOFF+SCG1+SCG0,SR ; Enter LPM3
;    ...                          ; Program stops here
;
; Exit LPM3 Interrupt Service Routine
    BIC    #CPUOFF+SCG1+SCG0,0(SP) ; Exit LPM3 on RETI
    RETI
```

2.4 Principles for Low-Power Applications

Often, the most important factor for reducing power consumption is using the MSP430's clock system to maximize the time in LPM3. LPM3 power consumption is less than 2 μ A typical with both a real-time clock function and all interrupts active. A 32-kHz watch crystal is used for the ACLK and the CPU is clocked from the DCO (normally off) which has a 6- μ s wake-up.

- ☐ Use interrupts to wake the processor and control program flow.
- ☐ Peripherals should be switched on only when needed.
- ☐ Use low-power integrated peripheral modules in place of software driven functions. For example Timer_A and Timer_B can automatically generate PWM and capture external timing, with no CPU resources.
- ☐ Calculated branching and fast table look-ups should be used in place of flag polling and long software calculations.
- ☐ Avoid frequent subroutine and function calls due to overhead.
- ☐ For longer software routines, single-cycle CPU registers should be used.

2.5 Connection of Unused Pins

The correct termination of all unused pins is listed in Table 2–2.

Table 2–2. Connection of Unused Pins

Pin	Potential	Comment
AV _{CC}	DV _{CC}	
AV _{SS}	DV _{SS}	
V _{REF+}	Open	
Ve _{REF+}	DV _{SS}	
V _{REF-} /Ve _{REF-}	DV _{SS}	
XIN	DV _{CC}	
XOUT	Open	
XT2IN	DV _{SS}	
XT2OUT	Open	
Px.0 to Px.7	Open	Switched to port function, output direction or input with pull-up/down enabled
$\overline{\text{RST}}/\text{NMI}$	DV _{CC} or V _{CC}	47 k Ω pullup with 10nF pull down
Test	Open	21x1, 22xx devices
TDO	Open	
TDI	Open	
TMS	Open	
TCK	Open	

RISC 16-Bit CPU

This chapter describes the MSP430 CPU, addressing modes, and instruction set.

Topic	Page
3.1 CPU Introduction	3-2
3.2 CPU Registers	3-4
3.3 Addressing Modes	3-9
3.4 Instruction Set	3-17

3.1 CPU Introduction

The CPU incorporates features specifically designed for modern programming techniques such as calculated branching, table processing and the use of high-level languages such as C. The CPU can address the complete address range without paging.

The CPU features include:

- ☐ RISC architecture with 27 instructions and 7 addressing modes
- ☐ Orthogonal architecture with every instruction usable with every addressing mode
- ☐ Full register access including program counter, status registers, and stack pointer
- ☐ Single-cycle register operations
- ☐ Large 16-bit register file reduces fetches to memory
- ☐ 16-bit address bus allows direct access and branching throughout entire memory range
- ☐ 16-bit data bus allows direct manipulation of word-wide arguments
- ☐ Constant generator provides six most used immediate values and reduces code size
- ☐ Direct memory-to-memory transfers without intermediate register holding
- ☐ Word and byte addressing and instruction formats

The block diagram of the CPU is shown in Figure 3–1.

Figure 3–1. CPU Block Diagram

3.2 CPU Registers

The CPU incorporates sixteen 16-bit registers. R0, R1, R2 and R3 have dedicated functions. R4 to R15 are working registers for general use.

3.2.1 Program Counter (PC)

The 16-bit program counter (PC/R0) points to the next instruction to be executed. Each instruction uses an even number of bytes (two, four, or six), and the PC is incremented accordingly. Instruction accesses in the 64-KB address space are performed on word boundaries, and the PC is aligned to even addresses. Figure 3–2 shows the program counter.

Figure 3–2. Program Counter

The PC can be addressed with all instructions and addressing modes. A few examples:

```
MOV    #LABEL,PC ; Branch to address LABEL
MOV    LABEL,PC  ; Branch to address contained in LABEL
MOV    @R14,PC   ; Branch indirect to address in R14
```

3.2.2 Stack Pointer (SP)

The stack pointer (SP/R1) is used by the CPU to store the return addresses of subroutine calls and interrupts. It uses a predecrement, postincrement scheme. In addition, the SP can be used by software with all instructions and addressing modes. Figure 3–3 shows the SP. The SP is initialized into RAM by the user, and is aligned to even addresses.

Figure 3–4 shows stack usage.

Figure 3–3. Stack Pointer

```

MOV    2(SP),R6 ; Item I2 -> R6
MOV    R7,0(SP) ; Overwrite TOS with R7
PUSH   #0123h   ; Put 0123h onto TOS
POP    R8        ; R8 = 0123h

```

Figure 3–4. Stack Usage

The special cases of using the SP as an argument to the PUSH and POP instructions are described and shown in Figure 3–5.

Figure 3–5. PUSH SP - POP SP Sequence

The stack pointer is changed after a PUSH SP instruction.

The stack pointer is not changed after a POP SP instruction. The POP SP instruction places SP1 into the stack pointer SP (SP2=SP1)

3.2.3 Status Register (SR)

The status register (SR/R2), used as a source or destination register, can be used in the register mode only addressed with word instructions. The remaining combinations of addressing modes are used to support the constant generator. Figure 3–6 shows the SR bits.

Figure 3–6. Status Register Bits

Table 3–1 describes the status register bits.

Table 3–1. Description of Status Register Bits

Bit	Description
V	<p>Overflow bit. This bit is set when the result of an arithmetic operation overflows the signed-variable range.</p> <p>ADD (.B) , ADDC (.B) Set when: Positive + Positive = Negative Negative + Negative = Positive, otherwise reset</p> <p>SUB (.B) , SUBC (.B) , CMP (.B) Set when: Positive – Negative = Negative Negative – Positive = Positive, otherwise reset</p>
SCG1	System clock generator 1. This bit, when set, turns off the SMCLK.
SCG0	System clock generator 0. This bit, when set, turns off the DCO dc generator, if DCOCLK is not used for MCLK or SMCLK.
OSCOFF	Oscillator Off. This bit, when set, turns off the LFXT1 crystal oscillator, when LFXT1CLK is not use for MCLK or SMCLK
CPUOFF	CPU off. This bit, when set, turns off the CPU.
GIE	General interrupt enable. This bit, when set, enables maskable interrupts. When reset, all maskable interrupts are disabled.
N	<p>Negative bit. This bit is set when the result of a byte or word operation is negative and cleared when the result is not negative.</p> <p>Word operation: N is set to the value of bit 15 of the result</p> <p>Byte operation: N is set to the value of bit 7 of the result</p>
Z	Zero bit. This bit is set when the result of a byte or word operation is 0 and cleared when the result is not 0.
C	Carry bit. This bit is set when the result of a byte or word operation produced a carry and cleared when no carry occurred.

3.2.4 Constant Generator Registers CG1 and CG2

Six commonly-used constants are generated with the constant generator registers R2 and R3, without requiring an additional 16-bit word of program code. The constants are selected with the source-register addressing modes (As), as described in Table 3–2.

Table 3–2. Values of Constant Generators CG1, CG2

Register	As	Constant	Remarks
R2	00	-----	Register mode
R2	01	(0)	Absolute address mode
R2	10	00004h	+4, bit processing
R2	11	00008h	+8, bit processing
R3	00	00000h	0, word processing
R3	01	00001h	+1
R3	10	00002h	+2, bit processing
R3	11	0FFFFh	–1, word processing

The constant generator advantages are:

- ☐ No special instructions required
- ☐ No additional code word for the six constants
- ☐ No code memory access required to retrieve the constant

The assembler uses the constant generator automatically if one of the six constants is used as an immediate source operand. Registers R2 and R3, used in the constant mode, cannot be addressed explicitly; they act as source-only registers.

Constant Generator – Expanded Instruction Set

The RISC instruction set of the MSP430 has only 27 instructions. However, the constant generator allows the MSP430 assembler to support 24 additional, emulated instructions. For example, the single-operand instruction:

CLR dst

is emulated by the double-operand instruction with the same length:

MOV R3, dst

where the #0 is replaced by the assembler, and R3 is used with As=00.

INC dst

is replaced by:

ADD 0 (R3) , dst

3.2.5 General-Purpose Registers R4 - R15

The twelve registers, R4–R15, are general-purpose registers. All of these registers can be used as data registers, address pointers, or index values and can be accessed with byte or word instructions as shown in Figure 3–7.

Figure 3–7. Register-Byte/Byte-Register Operations

3.3 Addressing Modes

Seven addressing modes for the source operand and four addressing modes for the destination operand can address the complete address space with no exceptions. The bit numbers in Table 3–3 describe the contents of the As (source) and Ad (destination) mode bits.

Table 3–3. Source/Destination Operand Addressing Modes

As/Ad	Addressing Mode	Syntax	Description
00/0	Register mode	Rn	Register contents are operand
01/1	Indexed mode	X(Rn)	(Rn + X) points to the operand. X is stored in the next word.
01/1	Symbolic mode	ADDR	(PC + X) points to the operand. X is stored in the next word. Indexed mode X(PC) is used.
01/1	Absolute mode	&ADDR	The word following the instruction contains the absolute address. X is stored in the next word. Indexed mode X(SR) is used.
10/–	Indirect register mode	@Rn	Rn is used as a pointer to the operand.
11/–	Indirect autoincrement	@Rn+	Rn is used as a pointer to the operand. Rn is incremented afterwards by 1 for .B instructions and by 2 for .W instructions.
11/–	Immediate mode	#N	The word following the instruction contains the immediate constant N. Indirect autoincrement mode @PC+ is used.

The seven addressing modes are explained in detail in the following sections. Most of the examples show the same addressing mode for the source and destination, but any valid combination of source and destination addressing modes is possible in an instruction.

Note: Use of Labels *EDE*, *TONI*, *TOM*, and *LEO*

Throughout MSP430 documentation *EDE*, *TONI*, *TOM*, and *LEO* are used as generic labels. They are only labels. They have no special meaning.

3.3.1 Register Mode

The register mode is described in Table 3–4.

Table 3–4. Register Mode Description

Assembler Code	Content of ROM
MOV R10, R11	MOV R10, R11

Length: One or two words

Operation: Move the content of R10 to R11. R10 is not affected.

Comment: Valid for source and destination

Example: MOV R10, R11

Before:		After:	
R10	0A023h	R10	0A023h
R11	0FA15h	R11	0A023h
PC	PC _{old}	PC	PC _{old} + 2

Note: Data in Registers

The data in the register can be accessed using word or byte instructions. If byte instructions are used, the high byte is always 0 in the result. The status bits are handled according to the result of the byte instruction.

3.3.2 Indexed Mode

The indexed mode is described in Table 3–5.

Table 3–5. Indexed Mode Description

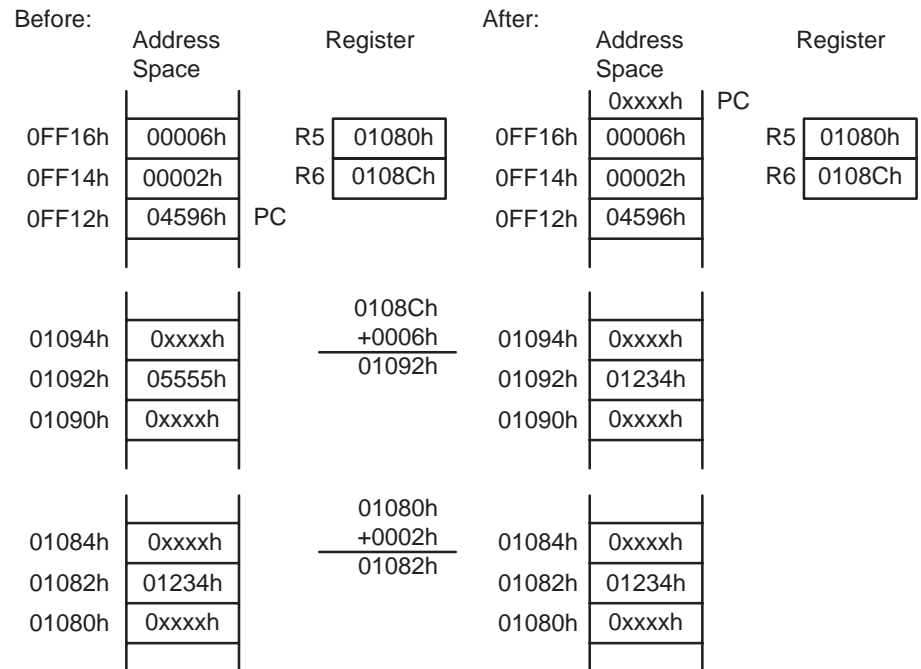

Assembler Code	Content of ROM
MOV 2 (R5) , 6 (R6)	MOV X (R5) , Y (R6)
	X = 2
	Y = 6

Length: Two or three words

Operation: Move the contents of the source address (contents of R5 + 2) to the destination address (contents of R6 + 6). The source and destination registers (R5 and R6) are not affected. In indexed mode, the program counter is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV 2 (R5) , 6 (R6) ;

3.3.3 Symbolic Mode

The symbolic mode is described in Table 3–6.

Table 3–6. Symbolic Mode Description

Assembler Code	Content of ROM
MOV EDE, TONI	MOV X(PC), Y(PC)
	X = EDE – PC
	Y = TONI – PC

Length: Two or three words

Operation: Move the contents of the source address EDE (contents of PC + X) to the destination address TONI (contents of PC + Y). The words after the instruction contain the differences between the PC and the source or destination addresses. The assembler computes and inserts offsets X and Y automatically. With symbolic mode, the program counter (PC) is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV EDE, TONI ;Source address EDE = 0F016h
;Dest. address TONI=01114h

Before:	Address Space	Register	After:	Address Space	Register
				0xxxxh	PC
0FF16h	011FEh		0FF16h	011FEh	
0FF14h	0F102h		0FF14h	0F102h	
0FF12h	04090h	PC	0FF12h	04090h	
0F018h	0xxxxh	0FF14h +0F102h 0F016h	0F018h	0xxxxh	
0F016h	0A123h		0F016h	0A123h	
0F014h	0xxxxh		0F014h	0xxxxh	
01116h	0xxxxh	0FF16h +011FEh 01114h	01116h	0xxxxh	
01114h	05555h		01114h	0A123h	
01112h	0xxxxh		01112h	0xxxxh	

3.3.4 Absolute Mode

The absolute mode is described in Table 3–7.

Table 3–7. Absolute Mode Description

Assembler Code	Content of ROM
MOV &EDE, &TONI	MOV X(0), Y(0) X = EDE Y = TONI

Length: Two or three words

Operation: Move the contents of the source address EDE to the destination address TONI. The words after the instruction contain the absolute address of the source and destination addresses. With absolute mode, the PC is incremented automatically so that program execution continues with the next instruction.

Comment: Valid for source and destination

Example: MOV &EDE, &TONI ;Source address EDE=0F016h,
;dest. address TONI=01114h

Before:	Address Space	Register	After:	Address Space	Register
				0xxxxh	PC
0FF16h	01114h		0FF16h	01114h	
0FF14h	0F016h		0FF14h	0F016h	
0FF12h	04292h	PC	0FF12h	04292h	
0F018h	0xxxxh		0F018h	0xxxxh	
0F016h	0A123h		0F016h	0A123h	
0F014h	0xxxxh		0F014h	0xxxxh	
01116h	0xxxxh		01116h	0xxxxh	
01114h	01234h		01114h	0A123h	
01112h	0xxxxh		01112h	0xxxxh	

This address mode is mainly for hardware peripheral modules that are located at an absolute, fixed address. These are addressed with absolute mode to ensure software transportability (for example, position-independent code).

3.3.5 Indirect Register Mode

The indirect register mode is described in Table 3–8.

Table 3–8. Indirect Mode Description

Assembler Code		Content of ROM	
MOV @R10, 0 (R11)		MOV @R10, 0 (R11)	

Length: One or two words

Operation: Move the contents of the source address (contents of R10) to the destination address (contents of R11). The registers are not modified.

Comment: Valid only for source operand. The substitute for destination operand is 0(Rd).

Example: MOV.B @R10, 0 (R11)

Before:

Address Space	Register
0xxxxh	
0FF16h	R10 0FA33h
0FF14h	PC R11 002A7h
0FF12h	
0FA34h	
0FA32h	
0FA30h	
002A8h	
002A7h	
002A6h	

After:

Address Space	Register
0xxxxh	PC
0FF16h	R10 0FA33h
0FF14h	R11 002A7h
0FF12h	
0FA34h	
0FA32h	
0FA30h	
002A8h	
002A7h	
002A6h	

3.3.6 Indirect Autoincrement Mode

The indirect autoincrement mode is described in Table 3–9.

Table 3–9. Indirect Autoincrement Mode Description

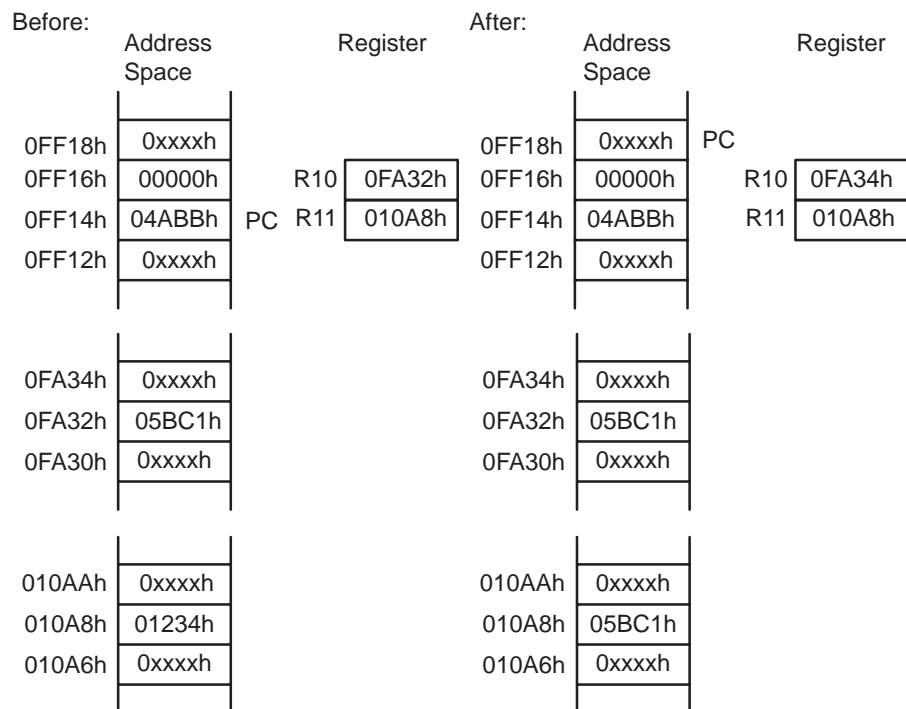

Assembler Code	Content of ROM
MOV @R10+, 0 (R11)	MOV @R10+, 0 (R11)

Length: One or two words

Operation: Move the contents of the source address (contents of R10) to the destination address (contents of R11). Register R10 is incremented by 1 for a byte operation, or 2 for a word operation after the fetch; it points to the next address without any overhead. This is useful for table processing.

Comment: Valid only for source operand. The substitute for destination operand is 0(Rd) plus second instruction INCD Rd.

Example: MOV @R10+, 0 (R11)

The autoincrementing of the register contents occurs after the operand is fetched. This is shown in Figure 3–8.

Figure 3–8. Operand Fetch Operation

3.3.7 Immediate Mode

The immediate mode is described in Table 3–10.

Table 3–10. Immediate Mode Description

Assembler Code	Content of ROM
MOV #45h, TONI	MOV @PC+, X (PC)
	45
	$X = \text{TONI} - \text{PC}$

Length: Two or three words
It is one word less if a constant of CG1 or CG2 can be used.

Operation: Move the immediate constant 45h, which is contained in the word following the instruction, to destination address TONI. When fetching the source, the program counter points to the word following the instruction and moves the contents to the destination.

Comment: Valid only for a source operand.

Example: MOV #45h, TONI

Before:	Address Space	Register	After:	Address Space	Register
0FF16h	01192h		0FF18h	0xxxxh	PC
0FF14h	00045h		0FF16h	01192h	
0FF12h	040B0h	PC	0FF14h	00045h	
			0FF12h	040B0h	
010AAh	0xxxxh		010AAh	0xxxxh	
010A8h	01234h	$\begin{array}{r} 0FF16h \\ +01192h \\ \hline 010A8h \end{array}$	010A8h	00045h	
010A6h	0xxxxh		010A6h	0xxxxh	

3.4 Instruction Set

The complete MSP430 instruction set consists of 27 core instructions and 24 emulated instructions. The core instructions are instructions that have unique op-codes decoded by the CPU. The emulated instructions are instructions that make code easier to write and read, but do not have op-codes themselves, instead they are replaced automatically by the assembler with an equivalent core instruction. There is no code or performance penalty for using emulated instruction.

There are three core-instruction formats:

- ☐ Dual-operand
- ☐ Single-operand
- ☐ Jump

All single-operand and dual-operand instructions can be byte or word instructions by using .B or .W extensions. Byte instructions are used to access byte data or byte peripherals. Word instructions are used to access word data or word peripherals. If no extension is used, the instruction is a word instruction.

The source and destination of an instruction are defined by the following fields:

src	The source operand defined by As and S-reg
dst	The destination operand defined by Ad and D-reg
As	The addressing bits responsible for the addressing mode used for the source (src)
S-reg	The working register used for the source (src)
Ad	The addressing bits responsible for the addressing mode used for the destination (dst)
D-reg	The working register used for the destination (dst)
B/W	Byte or word operation: 0: word operation 1: byte operation

Note: Destination Address

Destination addresses are valid anywhere in the memory map. However, when using an instruction that modifies the contents of the destination, the user must ensure the destination address is writable. For example, a masked-ROM location would be a valid destination address, but the contents are not modifiable, so the results of the instruction would be lost.

3.4.1 Double-Operand (Format I) Instructions

Figure 3–9 illustrates the double-operand instruction format.

Figure 3–9. Double Operand Instruction Format

Table 3–11 lists and describes the double operand instructions.

Table 3–11. Double Operand Instructions

Mnemonic	S-Reg, D-Reg	Operation	Status Bits			
			V	N	Z	C
MOV (.B)	src, dst	src → dst	–	–	–	–
ADD (.B)	src, dst	src + dst → dst	*	*	*	*
ADDC (.B)	src, dst	src + dst + C → dst	*	*	*	*
SUB (.B)	src, dst	dst + .not.src + 1 → dst	*	*	*	*
SUBC (.B)	src, dst	dst + .not.src + C → dst	*	*	*	*
CMP (.B)	src, dst	dst – src	*	*	*	*
DADD (.B)	src, dst	src + dst + C → dst (decimally)	*	*	*	*
BIT (.B)	src, dst	src .and. dst	0	*	*	*
BIC (.B)	src, dst	.not.src .and. dst → dst	–	–	–	–
BIS (.B)	src, dst	src .or. dst → dst	–	–	–	–
XOR (.B)	src, dst	src .xor. dst → dst	*	*	*	*
AND (.B)	src, dst	src .and. dst → dst	0	*	*	*

- * The status bit is affected
- The status bit is not affected
- 0 The status bit is cleared
- 1 The status bit is set

Note: Instructions CMP and SUB

The instructions CMP and SUB are identical except for the storage of the result. The same is true for the BIT and AND instructions.

3.4.2 Single-Operand (Format II) Instructions

Figure 3–10 illustrates the single-operand instruction format.

Figure 3–10. Single Operand Instruction Format

Table 3–12 lists and describes the single operand instructions.

Table 3–12. Single Operand Instructions

Mnemonic	S-Reg, D-Reg	Operation	Status Bits			
			V	N	Z	C
RRC (.B)	dst	C → MSB →.....LSB → C	*	*	*	*
RRA (.B)	dst	MSB → MSB →....LSB → C	0	*	*	*
PUSH (.B)	src	SP – 2 → SP, src → @SP	–	–	–	–
SWPB	dst	Swap bytes	–	–	–	–
CALL	dst	SP – 2 → SP, PC+2 → @SP	–	–	–	–
		dst → PC				
RETI		TOS → SR, SP + 2 → SP	*	*	*	*
		TOS → PC, SP + 2 → SP				
SXT	dst	Bit 7 → Bit 8.....Bit 15	0	*	*	*

- * The status bit is affected
- The status bit is not affected
- 0 The status bit is cleared
- 1 The status bit is set

All addressing modes are possible for the `CALL` instruction. If the symbolic mode (ADDRESS), the immediate mode (#N), the absolute mode (&EDE) or the indexed mode x(RN) is used, the word that follows contains the address information.

3.4.3 Jumps

Figure 3–11 shows the conditional-jump instruction format.

Figure 3–11. Jump Instruction Format

Table 3–13 lists and describes the jump instructions.

Table 3–13. Jump Instructions

Mnemonic	S-Reg, D-Reg	Operation
JEQ/JZ	Label	Jump to label if zero bit is set
JNE/JNZ	Label	Jump to label if zero bit is reset
JC	Label	Jump to label if carry bit is set
JNC	Label	Jump to label if carry bit is reset
JN	Label	Jump to label if negative bit is set
JGE	Label	Jump to label if (N .XOR. V) = 0
JL	Label	Jump to label if (N .XOR. V) = 1
JMP	Label	Jump to label unconditionally

Conditional jumps support program branching relative to the PC and do not affect the status bits. The possible jump range is from –511 to +512 words relative to the PC value at the jump instruction. The 10-bit program-counter offset is treated as a signed 10-bit value that is doubled and added to the program counter:

$$PC_{\text{new}} = PC_{\text{old}} + 2 + PC_{\text{offset}} \times 2$$

* ADC[W]	Add carry to destination
* ADC.B	Add carry to destination
Syntax	ADC dst or ADC.W dst ADC.B dst
Operation	dst + C → dst
Emulation	ADDC #0,dst ADDC.B #0,dst
Description	The carry bit (C) is added to the destination operand. The previous contents of the destination are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if dst was incremented from 0FFFFh to 0000, reset otherwise Set if dst was incremented from 0FFh to 00, reset otherwise V: Set if an arithmetic overflow occurs, otherwise reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The 16-bit counter pointed to by R13 is added to a 32-bit counter pointed to by R12. ADD @R13,0(R12) ; Add LSDs ADC 2(R12) ; Add carry to MSD
Example	The 8-bit counter pointed to by R13 is added to a 16-bit counter pointed to by R12. ADD.B @R13,0(R12) ; Add LSDs ADC.B 1(R12) ; Add carry to MSD

ADD[.W]	Add source to destination				
ADD.B	Add source to destination				
Syntax	ADD	src,dst	or	ADD.W	src,dst
	ADD.B	src,dst			
Operation	src + dst -> dst				
Description	The source operand is added to the destination operand. The source operand is not affected. The previous contents of the destination are lost.				
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if there is a carry from the result, cleared if not V: Set if an arithmetic overflow occurs, otherwise reset				
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.				
Example	R5 is increased by 10. The jump to TONI is performed on a carry.				
	ADD	#10,R5			
	JC	TONI			; Carry occurred
				; No carry
Example	R5 is increased by 10. The jump to TONI is performed on a carry.				
	ADD.B	#10,R5			; Add 10 to Lowbyte of R5
	JC	TONI			; Carry occurred, if (R5) ≥ 246 [0Ah+0F6h]
				; No carry

ADDC[.W]	Add source and carry to destination
ADDC.B	Add source and carry to destination
Syntax	ADDC src,dst or ADDC.W src,dst ADDC.B src,dst
Operation	src + dst + C → dst
Description	The source operand and the carry bit (C) are added to the destination operand. The source operand is not affected. The previous contents of the destination are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if there is a carry from the MSB of the result, reset otherwise V: Set if an arithmetic overflow occurs, otherwise reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The 32-bit counter pointed to by R13 is added to a 32-bit counter, eleven words (20/2 + 2/2) above the pointer in R13. ADD @R13+,20(R13) ; ADD LSDs with no carry in ADDC @R13+,20(R13) ; ADD MSDs with carry ... ; resulting from the LSDs
Example	The 24-bit counter pointed to by R13 is added to a 24-bit counter, eleven words above the pointer in R13. ADD.B @R13+,10(R13) ; ADD LSDs with no carry in ADDC.B @R13+,10(R13) ; ADD medium Bits with carry ADDC.B @R13+,10(R13) ; ADD MSDs with carry ... ; resulting from the LSDs

AND[.W]	Source AND destination
AND.B	Source AND destination
Syntax	AND src,dst or AND.W src,dst AND.B src,dst
Operation	src .AND. dst → dst
Description	The source operand and the destination operand are logically ANDed. The result is placed into the destination.
Status Bits	N: Set if result MSB is set, reset if not set Z: Set if result is zero, reset otherwise C: Set if result is not zero, reset otherwise (= .NOT. Zero) V: Reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	<p>The bits set in R5 are used as a mask (#0AA55h) for the word addressed by TOM. If the result is zero, a branch is taken to label TONI.</p> <pre> MOV #0AA55h,R5 ; Load mask into register R5 AND R5,TOM ; mask word addressed by TOM with R5 JZ TONI ; ; Result is not zero ; ; ; ; ; or ; ; ; AND #0AA55h,TOM JZ TONI </pre>
Example	<p>The bits of mask #0A5h are logically ANDed with the low byte TOM. If the result is zero, a branch is taken to label TONI.</p> <pre> AND.B #0A5h,TOM ; mask Lowbyte TOM with 0A5h JZ TONI ; ; Result is not zero </pre>

BIC[W]	Clear bits in destination
BIC.B	Clear bits in destination
Syntax	BIC src,dst or BIC.W src,dst BIC.B src,dst
Operation	.NOT.src .AND. dst -> dst
Description	The inverted source operand and the destination operand are logically ANDed. The result is placed into the destination. The source operand is not affected.
Status Bits	Status bits are not affected.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The six MSBs of the RAM word LEO are cleared. BIC #0FC00h,LEO ; Clear 6 MSBs in MEM(LEO)
Example	The five MSBs of the RAM byte LEO are cleared. BIC.B #0F8h,LEO ; Clear 5 MSBs in Ram location LEO

BIS[W]	Set bits in destination
BIS.B	Set bits in destination
Syntax	<div> <div>BIS</div> <div>src,dst</div> </div> <div>or</div> <div> <div>BIS.W</div> <div>src,dst</div> </div> <div> <div>BIS.B</div> <div>src,dst</div> </div>
Operation	src .OR. dst -> dst
Description	The source operand and the destination operand are logically ORed. The result is placed into the destination. The source operand is not affected.
Status Bits	Status bits are not affected.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	<p>The six LSBs of the RAM word TOM are set.</p> <pre>BIS #003Fh,TOM; set the six LSBs in RAM location TOM</pre>
Example	<p>The three MSBs of RAM byte TOM are set.</p> <pre>BIS.B #0E0h,TOM ; set the 3 MSBs in RAM location TOM</pre>

BIT[.W]	Test bits in destination
BIT.B	Test bits in destination
Syntax	BIT src,dst or BIT.W src,dst
Operation	src .AND. dst
Description	The source and destination operands are logically ANDed. The result affects only the status bits. The source and destination operands are not affected.
Status Bits	N: Set if MSB of result is set, reset otherwise Z: Set if result is zero, reset otherwise C: Set if result is not zero, reset otherwise (.NOT. Zero) V: Reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	<p>If bit 9 of R8 is set, a branch is taken to label TOM.</p> <pre> BIT #0200h,R8 ; bit 9 of R8 set? JNZ TOM ; Yes, branch to TOM ... ; No, proceed </pre>
Example	<p>If bit 3 of R8 is set, a branch is taken to label TOM.</p> <pre> BIT.B #8,R8 JC TOM </pre>
Example	<p>A serial communication receive bit (RCV) is tested. Because the carry bit is equal to the state of the tested bit while using the BIT instruction to test a single bit, the carry bit is used by the subsequent instruction; the read information is shifted into register RECBUF.</p> <pre> ; ; Serial communication with LSB is shifted first: ; xxxx xxxx xxxx xxxx BIT.B #RCV,RCCTL ; Bit info into carry RRC RECBUF ; Carry -> MSB of RECBUF ; cxxx xxxx ; repeat previous two instructions ; 8 times ; cccc cccc ; ^ ^ ; MSB LSB ; Serial communication with MSB shifted first: BIT.B #RCV,RCCTL ; Bit info into carry RLC.B RECBUF ; Carry -> LSB of RECBUF ; xxxx xxxc ; repeat previous two instructions ; 8 times ; cccc cccc ; LSB ; MSB </pre>

* BR, BRANCH	Branch to destination	
Syntax	BR	dst
Operation	dst → PC	
Emulation	MOV	dst,PC
Description	An unconditional branch is taken to an address anywhere in the 64K address space. All source addressing modes can be used. The branch instruction is a word instruction.	
Status Bits	Status bits are not affected.	
Example	Examples for all addressing modes are given.	
	BR	#EXEC ; Branch to label EXEC or direct branch (e.g. #0A4h) ; Core instruction MOV @PC+,PC
	BR	EXEC ; Branch to the address contained in EXEC ; Core instruction MOV X(PC),PC ; Indirect address
	BR	&EXEC ; Branch to the address contained in absolute ; address EXEC ; Core instruction MOV X(0),PC ; Indirect address
	BR	R5 ; Branch to the address contained in R5 ; Core instruction MOV R5,PC ; Indirect R5
	BR	@R5 ; Branch to the address contained in the word ; pointed to by R5. ; Core instruction MOV @R5,PC ; Indirect, indirect R5
	BR	@R5+ ; Branch to the address contained in the word pointed ; to by R5 and increment pointer in R5 afterwards. ; The next time—S/W flow uses R5 pointer—it can ; alter program execution due to access to ; next address in a table pointed to by R5 ; Core instruction MOV @R5,PC ; Indirect, indirect R5 with autoincrement
	BR	X(R5) ; Branch to the address contained in the address ; pointed to by R5 + X (e.g. table with address ; starting at X). X can be an address or a label ; Core instruction MOV X(R5),PC ; Indirect, indirect R5 + X

CALL	Subroutine		
Syntax	CALL	dst	
Operation	dst	→ tmp	dst is evaluated and stored
	SP – 2	→ SP	
	PC	→ @SP	PC updated to TOS
	tmp	→ PC	dst saved to PC
Description	A subroutine call is made to an address anywhere in the 64K address space. All addressing modes can be used. The return address (the address of the following instruction) is stored on the stack. The call instruction is a word instruction.		
Status Bits	Status bits are not affected.		
Example	Examples for all addressing modes are given.		
CALL	#EXEC	; Call on label EXEC or immediate address (e.g. #0A4h) ; SP-2 → SP, PC+2 → @SP, @PC+ → PC	
CALL	EXEC	; Call on the address contained in EXEC ; SP-2 → SP, PC+2 → @SP, X(PC) → PC ; Indirect address	
CALL	&EXEC	; Call on the address contained in absolute address ; EXEC ; SP-2 → SP, PC+2 → @SP, X(0) → PC ; Indirect address	
CALL	R5	; Call on the address contained in R5 ; SP-2 → SP, PC+2 → @SP, R5 → PC ; Indirect R5	
CALL	@R5	; Call on the address contained in the word ; pointed to by R5 ; SP-2 → SP, PC+2 → @SP, @R5 → PC ; Indirect, indirect R5	
CALL	@R5+	; Call on the address contained in the word ; pointed to by R5 and increment pointer in R5. ; The next time—S/W flow uses R5 pointer— ; it can alter the program execution due to ; access to next address in a table pointed to by R5 ; SP-2 → SP, PC+2 → @SP, @R5 → PC ; Indirect, indirect R5 with autoincrement	
CALL	X(R5)	; Call on the address contained in the address pointed ; to by R5 + X (e.g. table with address starting at X) ; X can be an address or a label ; SP-2 → SP, PC+2 → @SP, X(R5) → PC ; Indirect, indirect R5 + X	

* CLR[.W]	Clear destination		
* CLR.B	Clear destination		
Syntax	CLR	dst	or CLR.W dst
	CLR.B	dst	
Operation	0 → dst		
Emulation	MOV	#0,dst	
	MOV.B	#0,dst	
Description	The destination operand is cleared.		
Status Bits	Status bits are not affected.		
Example	RAM word TONI is cleared.		
	CLR	TONI	; 0 → TONI
Example	Register R5 is cleared.		
	CLR	R5	
Example	RAM byte TONI is cleared.		
	CLR.B	TONI	; 0 → TONI

* CLRC	Clear carry bit
Syntax	CLRC
Operation	0 → C
Emulation	BIC #1,SR
Description	The carry bit (C) is cleared. The clear carry instruction is a word instruction.
Status Bits	N: Not affected Z: Not affected C: Cleared V: Not affected
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	<p>The 16-bit decimal counter pointed to by R13 is added to a 32-bit counter pointed to by R12.</p> <pre>CLRC ; C=0: defines start DADD @R13,0(R12) ; add 16-bit counter to low word of 32-bit counter DADC 2(R12) ; add carry to high word of 32-bit counter</pre>

* CLRN	Clear negative bit
Syntax	CLRN
Operation	0 → N or (.NOT.src .AND. dst → dst)
Emulation	BIC #4,SR
Description	The constant 04h is inverted (0FFFBh) and is logically ANDed with the destination operand. The result is placed into the destination. The clear negative bit instruction is a word instruction.
Status Bits	N: Reset to 0 Z: Not affected C: Not affected V: Not affected
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The Negative bit in the status register is cleared. This avoids special treatment with negative numbers of the subroutine called.
	CLRN
	CALL SUBR

SUBR	JN SUBRET ; If input is negative: do nothing and return

SUBRET	RET

* CLRZ	Clear zero bit
Syntax	CLRZ
Operation	$0 \rightarrow Z$ or (.NOT.src .AND. dst \rightarrow dst)
Emulation	BIC #2,SR
Description	The constant 02h is inverted (0FFFDh) and logically ANDed with the destination operand. The result is placed into the destination. The clear zero bit instruction is a word instruction.
Status Bits	N: Not affected Z: Reset to 0 C: Not affected V: Not affected
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The zero bit in the status register is cleared. CLRZ

CMP[.W]	Compare source and destination				
CMP.B	Compare source and destination				
Syntax	CMP	src,dst	or	CMP.W	src,dst
	CMP.B	src,dst			
Operation	dst + .NOT.src + 1 or (dst – src)				
Description	The source operand is subtracted from the destination operand. This is accomplished by adding the 1s complement of the source operand plus 1. The two operands are not affected and the result is not stored; only the status bits are affected.				
Status Bits	N: Set if result is negative, reset if positive (src >= dst) Z: Set if result is zero, reset otherwise (src = dst) C: Set if there is a carry from the MSB of the result, reset otherwise V: Set if an arithmetic overflow occurs, otherwise reset				
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.				
Example	R5 and R6 are compared. If they are equal, the program continues at the label EQUAL.				
	CMP	R5,R6		; R5 = R6?	
	JEQ	EQUAL		; YES, JUMP	
Example	Two RAM blocks are compared. If they are not equal, the program branches to the label ERROR.				
		MOV	#NUM,R5		; number of words to be compared
		MOV	#BLOCK1,R6		; BLOCK1 start address in R6
		MOV	#BLOCK2,R7		; BLOCK2 start address in R7
L\$1		CMP	@R6+,0(R7)		; Are Words equal? R6 increments
		JNZ	ERROR		; No, branch to ERROR
		INCD	R7		; Increment R7 pointer
		DEC	R5		; Are all words compared?
		JNZ	L\$1		; No, another compare
Example	The RAM bytes addressed by EDE and TONI are compared. If they are equal, the program continues at the label EQUAL.				
	CMP.B	EDE,TONI		; MEM(EDE) = MEM(TONI)?	
	JEQ	EQUAL		; YES, JUMP	

* DADC[W]	Add carry decimally to destination		
* DADC.B	Add carry decimally to destination		
Syntax	DADC	dst or DADC.W	src,dst
	DADC.B	dst	
Operation	dst + C → dst (decimally)		
Emulation	DADD	#0,dst	
	DADD.B	#0,dst	
Description	The carry bit (C) is added decimally to the destination.		
Status Bits	N: Set if MSB is 1 Z: Set if dst is 0, reset otherwise C: Set if destination increments from 9999 to 0000, reset otherwise Set if destination increments from 99 to 00, reset otherwise V: Undefined		
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.		
Example	The four-digit decimal number contained in R5 is added to an eight-digit decimal number pointed to by R8. <pre> CLRC ; Reset carry ; next instruction's start condition is defined DADD R5,0(R8) ; Add LSDs + C DADC 2(R8) ; Add carry to MSD </pre>		
Example	The two-digit decimal number contained in R5 is added to a four-digit decimal number pointed to by R8. <pre> CLRC ; Reset carry ; next instruction's start condition is defined DADD.B R5,0(R8) ; Add LSDs + C DADC 1(R8) ; Add carry to MSDs </pre>		

DADD[W]	Source and carry added decimally to destination
DADD.B	Source and carry added decimally to destination
Syntax	DADD src,dst or DADD.W src,dst DADD.B src,dst
Operation	src + dst + C → dst (decimally)
Description	The source operand and the destination operand are treated as four binary coded decimals (BCD) with positive signs. The source operand and the carry bit (C) are added decimally to the destination operand. The source operand is not affected. The previous contents of the destination are lost. The result is not defined for non-BCD numbers.
Status Bits	N: Set if the MSB is 1, reset otherwise Z: Set if result is zero, reset otherwise C: Set if the result is greater than 9999 Set if the result is greater than 99 V: Undefined
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The eight-digit BCD number contained in R5 and R6 is added decimally to an eight-digit BCD number contained in R3 and R4 (R6 and R4 contain the MSDs). <pre> CLRC ; clear carry DADD R5,R3 ; add LSDs DADD R6,R4 ; add MSDs with carry JC OVERFLOW ; If carry occurs go to error handling routine </pre>
Example	The two-digit decimal counter in the RAM byte CNT is incremented by one. <pre> CLRC ; clear carry DADD.B #1,CNT ; increment decimal counter </pre> <p>or</p> <pre> SETC DADD.B #0,CNT ; ≡ DADC.B CNT </pre>

* DEC[W]	Decrement destination
* DEC.B	Decrement destination
Syntax	DEC dst or DEC.W dst DEC.B dst
Operation	dst – 1 → dst
Emulation	SUB #1,dst
Emulation	SUB.B #1,dst
Description	The destination operand is decremented by one. The original contents are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if dst contained 1, reset otherwise C: Reset if dst contained 0, set otherwise V: Set if an arithmetic overflow occurs, otherwise reset. Set if initial value of destination was 08000h, otherwise reset. Set if initial value of destination was 080h, otherwise reset.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R10 is decremented by 1 DEC R10 ; Decrement R10 ; Move a block of 255 bytes from memory location starting with EDE to memory location starting with ; TONI. Tables should not overlap: start of destination address TONI must not be within the range EDE ; to EDE+0FEh ; L\$1 MOV #EDE,R6 MOV #255,R10 MOV.B @R6+,TONI-EDE-1(R6) DEC R10 JNZ L\$1 ; Do not transfer tables using the routine above with the overlap shown in Figure 3–12.

Figure 3–12. Decrement Overlap

* DECD[.W]	Double-decrement destination
* DECD.B	Double-decrement destination
Syntax	DECD dst or DECD.W dst DECD.B dst
Operation	dst – 2 → dst
Emulation	SUB #2,dst
Emulation	SUB.B #2,dst
Description	The destination operand is decremented by two. The original contents are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if dst contained 2, reset otherwise C: Reset if dst contained 0 or 1, set otherwise V: Set if an arithmetic overflow occurs, otherwise reset. Set if initial value of destination was 08001 or 08000h, otherwise reset. Set if initial value of destination was 081 or 080h, otherwise reset.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R10 is decremented by 2.

```
DECD        R10        ; Decrement R10 by two
```

```
; Move a block of 255 words from memory location starting with EDE to memory location
; starting with TONI
; Tables should not overlap: start of destination address TONI must not be within the
; range EDE to EDE+0FEh
;
```

```
MOV        #EDE,R6
MOV        #510,R10
L$1        MOV        @R6+,TONI-EDE-2(R6)
DECD        R10
JNZ        L$1
```

Example Memory at location LEO is decremented by two.

```
DECD.B      LEO        ; Decrement MEM(LEO)
```

Decrement status byte STATUS by two.

```
DECD.B      STATUS
```

* DINT	Disable (general) interrupts
Syntax	DINT
Operation	0 → GIE or (0FFF7h .AND. SR → SR / .NOT.src .AND. dst → dst)
Emulation	BIC #8,SR
Description	All interrupts are disabled. The constant 08h is inverted and logically ANDed with the status register (SR). The result is placed into the SR.
Status Bits	Status bits are not affected.
Mode Bits	GIE is reset. OSCOFF and CPUOFF are not affected.
Example	<p>The general interrupt enable (GIE) bit in the status register is cleared to allow a nondisrupted move of a 32-bit counter. This ensures that the counter is not modified during the move by any interrupt.</p> <pre> DINT ; All interrupt events using the GIE bit are disabled NOP MOV COUNTHI,R5 ; Copy counter MOV COUNTLO,R6 EINT ; All interrupt events using the GIE bit are enabled </pre>

Note: Disable Interrupt

If any code sequence needs to be protected from interruption, the DINT should be executed at least one instruction before the beginning of the uninterruptible sequence, or should be followed by a NOP instruction.

* EINT	Enable (general) interrupts
Syntax	EINT
Operation	1 → GIE or (0008h .OR. SR → SR / .src .OR. dst → dst)
Emulation	BIS #8,SR
Description	All interrupts are enabled. The constant #08h and the status register SR are logically ORed. The result is placed into the SR.
Status Bits	Status bits are not affected.
Mode Bits	GIE is set. OSCOFF and CPUOFF are not affected.
Example	The general interrupt enable (GIE) bit in the status register is set.

```

; Interrupt routine of ports P1.2 to P1.7
; P1IN is the address of the register where all port bits are read. P1IFG is the address of
; the register where all interrupt events are latched.
;
      PUSH.B  &P1IN
      BIC.B   @SP,&P1IFG  ; Reset only accepted flags
      EINT                    ; Preset port 1 interrupt flags stored on stack
                           ; other interrupts are allowed

      BIT     #Mask,@SP
      JEQ     MaskOK       ; Flags are present identically to mask: jump
      .....
MaskOK  BIC     #Mask,@SP
      .....
      INCD    SP           ; Housekeeping: inverse to PUSH instruction
                           ; at the start of interrupt subroutine. Corrects
                           ; the stack pointer.

      RETI

```

Note: Enable Interrupt

The instruction following the enable interrupt instruction (EINT) is always executed, even if an interrupt service request is pending when the interrupts are enable.

* INC[.W]	Increment destination
* INC.B	Increment destination
Syntax	INC dst or INC.W dst INC.B dst
Operation	dst + 1 → dst
Emulation	ADD #1,dst
Description	The destination operand is incremented by one. The original contents are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if dst contained 0FFFFh, reset otherwise Set if dst contained 0FFh, reset otherwise C: Set if dst contained 0FFFFh, reset otherwise Set if dst contained 0FFh, reset otherwise V: Set if dst contained 07FFFh, reset otherwise Set if dst contained 07Fh, reset otherwise
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The status byte, STATUS, of a process is incremented. When it is equal to 11, a branch to OVFL is taken. <div style="margin-left: 100px;"> INC.B STATUS CMP.B #11,STATUS JEQ OVFL </div>

* INCD[.W]	Double-increment destination
* INCD.B	Double-increment destination
Syntax	INCD dst or INCD.W dst INCD.B dst
Operation	dst + 2 → dst
Emulation	ADD #2,dst
Emulation	ADD.B #2,dst
Example	The destination operand is incremented by two. The original contents are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if dst contained 0FFFEh, reset otherwise Set if dst contained 0FEh, reset otherwise C: Set if dst contained 0FFFEh or 0FFFFh, reset otherwise Set if dst contained 0FEh or 0FFh, reset otherwise V: Set if dst contained 07FFEh or 07FFFh, reset otherwise Set if dst contained 07Eh or 07Fh, reset otherwise
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The item on the top of the stack (TOS) is removed without using a register. PUSH R5 ; R5 is the result of a calculation, which is stored ; in the system stack INCD SP ; Remove TOS by double-increment from stack ; Do not use INCD.B, SP is a word-aligned ; register RET
Example	The byte on the top of the stack is incremented by two. INCD.B 0(SP) ; Byte on TOS is increment by two

* INV[.W]	Invert destination
* INV.B	Invert destination
Syntax	INV dst INV.B dst
Operation	.NOT.dst -> dst
Emulation	XOR #0FFFFh,dst
Emulation	XOR.B #0FFh,dst
Description	The destination operand is inverted. The original contents are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if dst contained 0FFFFh, reset otherwise Set if dst contained 0FFh, reset otherwise C: Set if result is not zero, reset otherwise (= .NOT. Zero) Set if result is not zero, reset otherwise (= .NOT. Zero) V: Set if initial destination operand was negative, otherwise reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	Content of R5 is negated (twos complement). MOV #00AEh,R5 ; R5 = 000AEh INV R5 ; Invert R5, R5 = 0FF51h INC R5 ; R5 is now negated, R5 = 0FF52h
Example	Content of memory byte LEO is negated. MOV.B #0AEh,LEO ; MEM(LEO) = 0AEh INV.B LEO ; Invert LEO, MEM(LEO) = 051h INC.B LEO ; MEM(LEO) is negated, MEM(LEO) = 052h

JC	Jump if carry set	
JHS	Jump if higher or same	
Syntax	JC	label
	JHS	label
Operation	If C = 1: $PC + 2 \times \text{offset} \rightarrow PC$ If C = 0: execute following instruction	
Description	The status register carry bit (C) is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If C is reset, the next instruction following the jump is executed. JC (jump if carry/higher or same) is used for the comparison of unsigned numbers (0 to 65536).	
Status Bits	Status bits are not affected.	
Example	The P1IN.1 signal is used to define or control the program flow.	
	BIT	#01h,&P1IN ; State of signal \rightarrow Carry
	JC	PROGA ; If carry=1 then execute program routine A
	; Carry=0, execute program here
Example	R5 is compared to 15. If the content is higher or the same, branch to LABEL.	
	CMP	#15,R5
	JHS	LABEL ; Jump is taken if $R5 \geq 15$
	; Continue here if $R5 < 15$

JEQ, JZ	Jump if equal, jump if zero
Syntax	JEQ label, JZ label
Operation	If Z = 1: PC + 2 × offset → PC If Z = 0: execute following instruction
Description	The status register zero bit (Z) is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If Z is not set, the instruction following the jump is executed.
Status Bits	Status bits are not affected.
Example	Jump to address TONI if R7 contains zero. TST R7 ; Test R7 JZ TONI ; if zero: JUMP
Example	Jump to address LEO if R6 is equal to the table contents. CMP R6,Table(R5) ; Compare content of R6 with content of ; MEM (table address + content of R5) JEQ LEO ; Jump if both data are equal ; No, data are not equal, continue here
Example	Branch to LABEL if R5 is 0. TST R5 JZ LABEL

JGE	Jump if greater or equal
Syntax	JGE label
Operation	If (N .XOR. V) = 0 then jump to label: PC + 2 × offset → PC If (N .XOR. V) = 1 then execute the following instruction
Description	The status register negative bit (N) and overflow bit (V) are tested. If both N and V are set or reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If only one is set, the instruction following the jump is executed. This allows comparison of signed integers.
Status Bits	Status bits are not affected.
Example	When the content of R6 is greater or equal to the memory pointed to by R7, the program continues at label EDE. <pre> CMP @R7,R6 ; R6 ≥ (R7)?, compare on signed numbers JGE EDE ; Yes, R6 ≥ (R7) ; No, proceed </pre>

JL	Jump if less
Syntax	JL label
Operation	If (N .XOR. V) = 1 then jump to label: PC + 2 × offset → PC If (N .XOR. V) = 0 then execute following instruction
Description	<p>The status register negative bit (N) and overflow bit (V) are tested. If only one is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If both N and V are set or reset, the instruction following the jump is executed.</p> <p>This allows comparison of signed integers.</p>
Status Bits	Status bits are not affected.
Example	<p>When the content of R6 is less than the memory pointed to by R7, the program continues at label EDE.</p> <pre> CMP @R7,R6 ; R6 < (R7)?, compare on signed numbers JL EDE ; Yes, R6 < (R7) ; No, proceed </pre>

JMP	Jump unconditionally
Syntax	JMP label
Operation	$PC + 2 \times \text{offset} \rightarrow PC$
Description	The 10-bit signed offset contained in the instruction LSBs is added to the program counter.
Status Bits	Status bits are not affected.
Hint:	This one-word instruction replaces the BRANCH instruction in the range of -511 to +512 words relative to the current program counter.

JN	Jump if negative	
Syntax	JN	label
Operation	if N = 1: $PC + 2 \times \text{offset} \rightarrow PC$ if N = 0: execute following instruction	
Description	The negative bit (N) of the status register is tested. If it is set, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If N is reset, the next instruction following the jump is executed.	
Status Bits	Status bits are not affected.	
Example	The result of a computation in R5 is to be subtracted from COUNT. If the result is negative, COUNT is to be cleared and the program continues execution in another path.	
	SUB	R5,COUNT ; COUNT – R5 → COUNT
	JN	L\$1 ; If negative continue with COUNT=0 at PC=L\$1
	; Continue with COUNT ≥ 0
	
	
	
L\$1	CLR	COUNT
	
	
	

JNC	Jump if carry not set		
JLO	Jump if lower		
Syntax	JNC	label	
	JLO	label	
Operation	if C = 0: PC + 2 × offset → PC if C = 1: execute following instruction		
Description	The status register carry bit (C) is tested. If it is reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If C is set, the next instruction following the jump is executed. JNC (jump if no carry/lower) is used for the comparison of unsigned numbers (0 to 65536).		
Status Bits	Status bits are not affected.		
Example	The result in R6 is added in BUFFER. If an overflow occurs, an error handling routine at address ERROR is used.		
ERROR	ADD	R6,BUFFER	; BUFFER + R6 → BUFFER
	JNC	CONT	; No carry, jump to CONT
		; Error handler start
		
		
CONT		
			; Continue with normal program flow
		
Example			
	Branch to STL2 if byte STATUS contains 1 or 0.		
	CMP.B	#2,STATUS	
	JLO	STL2	; STATUS < 2
		; STATUS ≥ 2, continue here

JNE	Jump if not equal		
JNZ	Jump if not zero		
Syntax	JNE	label	
	JNZ	label	
Operation	If Z = 0: PC + 2 × offset → PC If Z = 1: execute following instruction		
Description	The status register zero bit (Z) is tested. If it is reset, the 10-bit signed offset contained in the instruction LSBs is added to the program counter. If Z is set, the next instruction following the jump is executed.		
Status Bits	Status bits are not affected.		
Example	Jump to address TONI if R7 and R8 have different contents.		
	CMP	R7,R8	; COMPARE R7 WITH R8
	JNE	TONI	; if different: jump
		; if equal, continue

MOV[.W]	Move source to destination
MOV.B	Move source to destination
Syntax	MOV src,dst or MOV.W src,dst MOV.B src,dst
Operation	src -> dst
Description	The source operand is moved to the destination. The source operand is not affected. The previous contents of the destination are lost.
Status Bits	Status bits are not affected.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The contents of table EDE (word data) are copied to table TOM. The length of the tables must be 020h locations.
Loop	<pre> MOV #EDE,R10 ; Prepare pointer MOV #020h,R9 ; Prepare counter MOV @R10+,TOM-EDE-2(R10) ; Use pointer in R10 for both tables DEC R9 ; Decrement counter JNZ Loop ; Counter ≠ 0, continue copying ; Copying completed </pre>
Example	The contents of table EDE (byte data) are copied to table TOM. The length of the tables should be 020h locations
Loop	<pre> MOV #EDE,R10 ; Prepare pointer MOV #020h,R9 ; Prepare counter MOV.B @R10+,TOM-EDE-1(R10) ; Use pointer in R10 for ; both tables DEC R9 ; Decrement counter JNZ Loop ; Counter ≠ 0, continue ; copying ; Copying completed </pre>

* NOP	No operation
Syntax	NOP
Operation	None
Emulation	MOV #0, R3
Description	No operation is performed. The instruction may be used for the elimination of instructions during the software check or for defined waiting times.
Status Bits	Status bits are not affected.
	The NOP instruction is mainly used for two purposes:
	<input type="checkbox"/> To fill one, two, or three memory words
	<input type="checkbox"/> To adjust software timing

Note: Emulating No-Operation Instruction

Other instructions can emulate the NOP function while providing different numbers of instruction cycles and code words. Some examples are:

Examples:

MOV	#0,R3	; 1 cycle, 1 word
MOV	0(R4),0(R4)	; 6 cycles, 3 words
MOV	@R4,0(R4)	; 5 cycles, 2 words
BIC	#0,EDE(R4)	; 4 cycles, 2 words
JMP	\$+2	; 2 cycles, 1 word
BIC	#0,R5	; 1 cycle, 1 word

However, care should be taken when using these examples to prevent unintended results. For example, if MOV 0(R4), 0(R4) is used and the value in R4 is 120h, then a security violation will occur with the watchdog timer (address 120h) because the security key was not used.

* POP[W]	Pop word from stack to destination		
* POP.B	Pop byte from stack to destination		
Syntax	POP	dst	
	POP.B	dst	
Operation	@SP → temp SP + 2 → SP temp → dst		
Emulation	MOV	@SP+,dst	or MOV.W @SP+,dst
Emulation	MOV.B	@SP+,dst	
Description	The stack location pointed to by the stack pointer (TOS) is moved to the destination. The stack pointer is incremented by two afterwards.		
Status Bits	Status bits are not affected.		
Example	The contents of R7 and the status register are restored from the stack.		
	POP	R7	; Restore R7
	POP	SR	; Restore status register
Example	The contents of RAM byte LEO is restored from the stack.		
	POP.B	LEO	; The low byte of the stack is moved to LEO.
Example	The contents of R7 is restored from the stack.		
	POP.B	R7	; The low byte of the stack is moved to R7, ; the high byte of R7 is 00h
Example	The contents of the memory pointed to by R7 and the status register are restored from the stack.		
	POP.B	0(R7)	; The low byte of the stack is moved to the ; the byte which is pointed to by R7 : Example: R7 = 203h ; ; Mem(R7) = low byte of system stack : Example: R7 = 20Ah ; ; Mem(R7) = low byte of system stack
	POP	SR	; Last word on stack moved to the SR

Note: The System Stack Pointer

The system stack pointer (SP) is always incremented by two, independent of the byte suffix.

PUSH[.W]	Push word onto stack
PUSH.B	Push byte onto stack
Syntax	PUSH src or PUSH.W src PUSH.B src
Operation	SP – 2 → SP src → @SP
Description	The stack pointer is decremented by two, then the source operand is moved to the RAM word addressed by the stack pointer (TOS).
Status Bits	Status bits are not affected.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	The contents of the status register and R8 are saved on the stack. PUSH SR ; save status register PUSH R8 ; save R8
Example	The contents of the peripheral TCDAT is saved on the stack. PUSH.B &TCDAT ; save data from 8-bit peripheral module, ; address TCDAT, onto stack

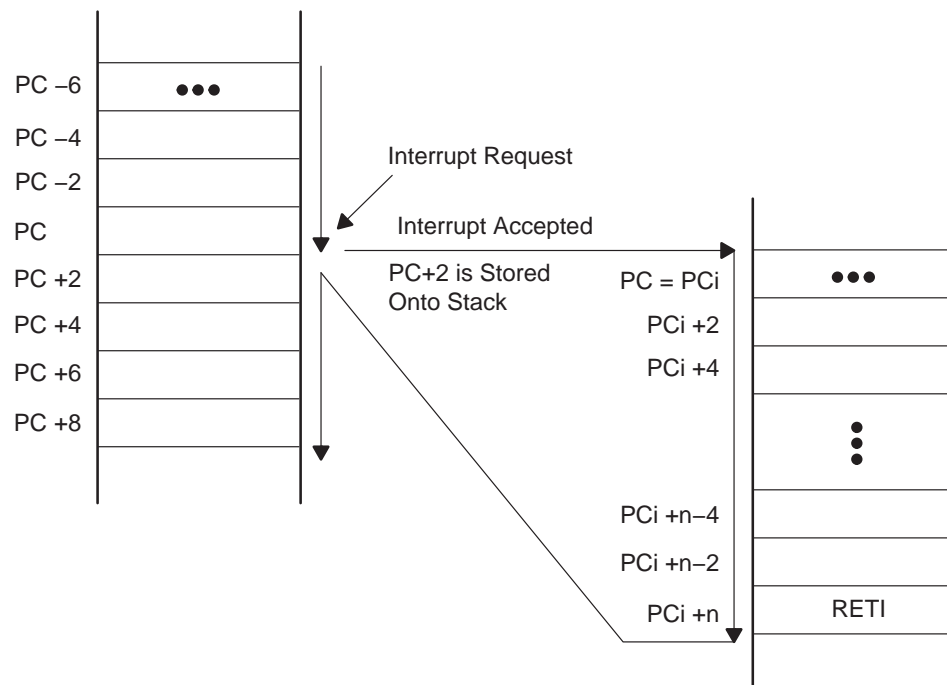

Note: The System Stack Pointer

The system stack pointer (SP) is always decremented by two, independent of the byte suffix.

* RET	Return from subroutine
Syntax	RET
Operation	@SP → PC SP + 2 → SP
Emulation	MOV @SP+, PC
Description	The return address pushed onto the stack by a CALL instruction is moved to the program counter. The program continues at the code address following the subroutine call.
Status Bits	Status bits are not affected.

RETI	Return from interrupt
Syntax	RETI
Operation	TOS → SR SP + 2 → SP TOS → PC SP + 2 → SP
Description	<p>The status register is restored to the value at the beginning of the interrupt service routine by replacing the present SR contents with the TOS contents. The stack pointer (SP) is incremented by two.</p> <p>The program counter is restored to the value at the beginning of interrupt service. This is the consecutive step after the interrupted program flow. Restoration is performed by replacing the present PC contents with the TOS memory contents. The stack pointer (SP) is incremented.</p>
Status Bits	N: restored from system stack Z: restored from system stack C: restored from system stack V: restored from system stack
Mode Bits	OSCOFF, CPUOFF, and GIE are restored from system stack.
Example	Figure 3–13 illustrates the main program interrupt.

Figure 3–13. Main Program Interrupt

* RLA[.W]	Rotate left arithmetically
* RLA.B	Rotate left arithmetically
Syntax	RLA dst or RLA.W dst RLA.B dst
Operation	$C \leftarrow \text{MSB} \leftarrow \text{MSB}-1 \dots \text{LSB}+1 \leftarrow \text{LSB} \leftarrow 0$
Emulation	ADD dst,dst ADD.B dst,dst
Description	<p>The destination operand is shifted left one position as shown in Figure 3–14. The MSB is shifted into the carry bit (C) and the LSB is filled with 0. The RLA instruction acts as a signed multiplication by 2.</p> <p>An overflow occurs if $\text{dst} \geq 04000\text{h}$ and $\text{dst} < 0\text{C}000\text{h}$ before operation is performed: the result has changed sign.</p>

Figure 3–14. Destination Operand—Arithmetic Shift Left

An overflow occurs if $\text{dst} \geq 040\text{h}$ and $\text{dst} < 0\text{C}0\text{h}$ before the operation is performed: the result has changed sign.

Status Bits	<p>N: Set if result is negative, reset if positive</p> <p>Z: Set if result is zero, reset otherwise</p> <p>C: Loaded from the MSB</p> <p>V: Set if an arithmetic overflow occurs: the initial value is $04000\text{h} \leq \text{dst} < 0\text{C}000\text{h}$; reset otherwise Set if an arithmetic overflow occurs: the initial value is $040\text{h} \leq \text{dst} < 0\text{C}0\text{h}$; reset otherwise</p>
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R7 is multiplied by 2.
	RLA R7 ; Shift left R7 ($\times 2$)
Example	The low byte of R7 is multiplied by 4.
	RLA.B R7 ; Shift left low byte of R7 ($\times 2$)
	RLA.B R7 ; Shift left low byte of R7 ($\times 4$)

Note: RLA Substitution

The assembler does not recognize the instruction:

RLA @R5+, RLA.B @R5+, or RLA(.B) @R5

It must be substituted by:

ADD @R5+,-2(R5) ADD.B @R5+,-1(R5) or ADD(.B) @R5

* RLC[.W]	Rotate left through carry
* RLC.B	Rotate left through carry
Syntax	RLC dst or RLC.W dst RLC.B dst
Operation	$C \leftarrow \text{MSB} \leftarrow \text{MSB}-1 \dots \text{LSB}+1 \leftarrow \text{LSB} \leftarrow C$
Emulation	ADDC dst,dst
Description	The destination operand is shifted left one position as shown in Figure 3–15. The carry bit (C) is shifted into the LSB and the MSB is shifted into the carry bit (C).

Figure 3–15. Destination Operand—Carry Left Shift

Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Loaded from the MSB V: Set if an arithmetic overflow occurs the initial value is $04000h \leq \text{dst} < 0C000h$; reset otherwise Set if an arithmetic overflow occurs: the initial value is $040h \leq \text{dst} < 0C0h$; reset otherwise
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R5 is shifted left one position.
	<pre>RLC R5 ; (R5 x 2) + C -> R5</pre>
Example	The input P1IN.1 information is shifted into the LSB of R5. <pre>BIT.B #2,&P1IN ; Information -> Carry RLC R5 ; Carry=P0in.1 -> LSB of R5</pre>
Example	The MEM(LEO) content is shifted left one position. <pre>RLC.B LEO ; Mem(LEO) x 2 + C -> Mem(LEO)</pre>

Note: RLC and RLC.B Substitution

The assembler does not recognize the instruction:

RLC @R5+, RLC.B @R5+, or RLC(.B) @R5

It must be substituted by:

ADDC @R5+,-2(R5) ADDC.B @R5+,-1(R5) or ADDC(.B) @R5

RRA[.W]	Rotate right arithmetically
RRA.B	Rotate right arithmetically
Syntax	RRA dst or RRA.W dst RRA.B dst
Operation	MSB → MSB, MSB → MSB-1, ... LSB+1 → LSB, LSB → C
Description	The destination operand is shifted right one position as shown in Figure 3-16. The MSB is shifted into the MSB, the MSB is shifted into the MSB-1, and the LSB+1 is shifted into the LSB.

Figure 3-16. Destination Operand—Arithmetic Right Shift

Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Loaded from the LSB V: Reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R5 is shifted right one position. The MSB retains the old value. It operates equal to an arithmetic division by 2. RRA R5 ; R5/2 → R5 ; The value in R5 is multiplied by 0.75 (0.5 + 0.25). ; PUSH R5 ; Hold R5 temporarily using stack RRA R5 ; R5 × 0.5 → R5 ADD @SP+,R5 ; R5 × 0.5 + R5 = 1.5 × R5 → R5 RRA R5 ; (1.5 × R5) × 0.5 = 0.75 × R5 → R5 Example The low byte of R5 is shifted right one position. The MSB retains the old value. It operates equal to an arithmetic division by 2. RRA.B R5 ; R5/2 → R5: operation is on low byte only ; High byte of R5 is reset PUSH.B R5 ; R5 × 0.5 → TOS RRA.B @SP ; TOS × 0.5 = 0.5 × R5 × 0.5 = 0.25 × R5 → TOS ADD.B @SP+,R5 ; R5 × 0.5 + R5 × 0.25 = 0.75 × R5 → R5

RRC[W]	Rotate right through carry
RRC.B	Rotate right through carry
Syntax	RRC dst or RRC.W dst RRC dst
Operation	C → MSB → MSB-1 LSB+1 → LSB → C
Description	The destination operand is shifted right one position as shown in Figure 3-17. The carry bit (C) is shifted into the MSB, the LSB is shifted into the carry bit (C).

Figure 3-17. Destination Operand—Carry Right Shift

Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Loaded from the LSB V: Reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	R5 is shifted right one position. The MSB is loaded with 1. SETC ; Prepare carry for MSB RRC R5 ; R5/2 + 8000h → R5
Example	R5 is shifted right one position. The MSB is loaded with 1. SETC ; Prepare carry for MSB RRC.B R5 ; R5/2 + 80h → R5; low byte of R5 is used

* SBC[.W]	Subtract source and borrow/.NOT. carry from destination		
* SBC.B	Subtract source and borrow/.NOT. carry from destination		
Syntax	SBC dst or SBC.W dst SBC.B dst		
Operation	dst + 0FFFFh + C → dst dst + 0FFh + C → dst		
Emulation	SUBC #0,dst SUBC.B #0,dst		
Description	The carry bit (C) is added to the destination operand minus one. The previous contents of the destination are lost.		
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if there is a carry from the MSB of the result, reset otherwise. Set to 1 if no borrow, reset if borrow. V: Set if an arithmetic overflow occurs, reset otherwise.		
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.		
Example	The 16-bit counter pointed to by R13 is subtracted from a 32-bit counter pointed to by R12.		
	SUB @R13,0(R12)	; Subtract LSDs	
	SBC 2(R12)	; Subtract carry from MSD	
Example	The 8-bit counter pointed to by R13 is subtracted from a 16-bit counter pointed to by R12.		
	SUB.B @R13,0(R12)	; Subtract LSDs	
	SBC.B 1(R12)	; Subtract carry from MSD	
<hr/>			
Note: Borrow Implementation.			
The borrow is treated as a .NOT. carry :		Borrow	Carry bit
		Yes	0
		No	1

* SETC	Set carry bit		
Syntax	SETC		
Operation	1 → C		
Emulation	BIS	#1,SR	
Description	The carry bit (C) is set.		
Status Bits	N: Not affected Z: Not affected C: Set V: Not affected		
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.		
Example	Emulation of the decimal subtraction: Subtract R5 from R6 decimally Assume that R5 = 03987h and R6 = 04137h		
DSUB	ADD	#06666h,R5	; Move content R5 from 0–9 to 6–0Fh ; R5 = 03987h + 06666h = 09FEDh ; Invert this (result back to 0–9) ; R5 = .NOT. R5 = 06012h ; Prepare carry = 1 ; Emulate subtraction by addition of: ; (010000h – R5 – 1) ; R6 = R6 + R5 + 1 ; R6 = 0150h
	INV	R5	
	SETC		
	DADD	R5,R6	

* SETN	Set negative bit
Syntax	SETN
Operation	1 → N
Emulation	BIS #4,SR
Description	The negative bit (N) is set.
Status Bits	N: Set Z: Not affected C: Not affected V: Not affected
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.

* SETZ	Set zero bit
Syntax	SETZ
Operation	1 → Z
Emulation	BIS #2,SR
Description	The zero bit (Z) is set.
Status Bits	N: Not affected Z: Set C: Not affected V: Not affected
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.

SUB[.W]	Subtract source from destination
SUB.B	Subtract source from destination
Syntax	SUB src,dst or SUB.W src,dst SUB.B src,dst
Operation	$\text{dst} + \text{.NOT.src} + 1 \rightarrow \text{dst}$ or $[(\text{dst} - \text{src} \rightarrow \text{dst})]$
Description	The source operand is subtracted from the destination operand by adding the source operand's 1s complement and the constant 1. The source operand is not affected. The previous contents of the destination are lost.
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if there is a carry from the MSB of the result, reset otherwise. Set to 1 if no borrow, reset if borrow. V: Set if an arithmetic overflow occurs, otherwise reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.
Example	See example at the SBC instruction.
Example	See example at the SBC.B instruction.

Note: Borrow Is Treated as a .NOT.

The borrow is treated as a .NOT. carry :	Borrow	Carry bit
	Yes	0
	No	1

SUBC[.W]SBB[.W]	Subtract source and borrow/.NOT. carry from destination				
SUBC.B,SBB.B	Subtract source and borrow/.NOT. carry from destination				
Syntax	SUBC	src,dst	or	SUBC.W	src,dst or
	SBB	src,dst	or	SBB.W	src,dst
	SUBC.B	src,dst	or	SBB.B	src,dst
Operation	dst + .NOT.src + C → dst or (dst – src – 1 + C → dst)				
Description	The source operand is subtracted from the destination operand by adding the source operand's 1s complement and the carry bit (C). The source operand is not affected. The previous contents of the destination are lost.				
Status Bits	N: Set if result is negative, reset if positive. Z: Set if result is zero, reset otherwise. C: Set if there is a carry from the MSB of the result, reset otherwise. Set to 1 if no borrow, reset if borrow. V: Set if an arithmetic overflow occurs, reset otherwise.				
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.				
Example	Two floating point mantissas (24 bits) are subtracted. LSBs are in R13 and R10, MSBs are in R12 and R9. SUB.W R13,R10 ; 16-bit part, LSBs SUBC.B R12,R9 ; 8-bit part, MSBs				
Example	The 16-bit counter pointed to by R13 is subtracted from a 16-bit counter in R10 and R11(MSD). SUB.B @R13+,R10 ; Subtract LSDs without carry SUBC.B @R13,R11 ; Subtract MSDs with carry ... ; resulting from the LSDs				

Note: Borrow Implementation

The borrow is treated as a .NOT. carry :		
	Borrow	Carry bit
	Yes	0
	No	1

SWPB	Swap bytes
Syntax	SWPB dst
Operation	Bits 15 to 8 <--> bits 7 to 0
Description	The destination operand high and low bytes are exchanged as shown in Figure 3–18.
Status Bits	Status bits are not affected.
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.

Figure 3–18. Destination Operand Byte Swap

**Example**

```
MOV    #040BFh,R7      ; 0100000010111111 -> R7
SWPB   R7               ; 1011111101000000 in R7
```

Example

The value in R5 is multiplied by 256. The result is stored in R5,R4.

```
SWPB   R5               ;
MOV     R5,R4           ;Copy the swapped value to R4
BIC     #0FF00h,R5      ;Correct the result
BIC     #00FFh,R4       ;Correct the result
```

SXT	Extend Sign
Syntax	SXT dst
Operation	Bit 7 → Bit 8 Bit 15
Description	The sign of the low byte is extended into the high byte as shown in Figure 3–19.
Status Bits	N: Set if result is negative, reset if positive Z: Set if result is zero, reset otherwise C: Set if result is not zero, reset otherwise (.NOT. Zero) V: Reset
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.

Figure 3–19. Destination Operand Sign Extension

Example

R7 is loaded with the P1IN value. The operation of the sign-extend instruction expands bit 8 to bit 15 with the value of bit 7.

R7 is then added to R6.

```
MOV.B   &P1IN,R7      ; P1IN = 080h:      . . . . . 1000 0000
SXT     R7              ; R7 = 0FF80h:    1111 1111 1000 0000
```

* TST[.W]	Test destination		
* TST.B	Test destination		
Syntax	TST	dst	or TST.W dst
	TST.B	dst	
Operation	dst + 0FFFFh + 1 dst + 0FFh + 1		
Emulation	CMP	#0,dst	
	CMP.B	#0,dst	
Description	The destination operand is compared with zero. The status bits are set according to the result. The destination is not affected.		
Status Bits	N: Set if destination is negative, reset if positive Z: Set if destination contains zero, reset otherwise C: Set V: Reset		
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.		
Example	R7 is tested. If it is negative, continue at R7NEG; if it is positive but not zero, continue at R7POS.		
	TST	R7	; Test R7
	JN	R7NEG	; R7 is negative
	JZ	R7ZERO	; R7 is zero
R7POS		; R7 is positive but not zero
R7NEG		; R7 is negative
R7ZERO		; R7 is zero
Example	The low byte of R7 is tested. If it is negative, continue at R7NEG; if it is positive but not zero, continue at R7POS.		
	TST.B	R7	; Test low byte of R7
	JN	R7NEG	; Low byte of R7 is negative
	JZ	R7ZERO	; Low byte of R7 is zero
R7POS		; Low byte of R7 is positive but not zero
R7NEG		; Low byte of R7 is negative
R7ZERO		; Low byte of R7 is zero

XOR[.W]	Exclusive OR of source with destination				
XOR.B	Exclusive OR of source with destination				
Syntax	XOR	src,dst	or	XOR.W	src,dst
	XOR.B	src,dst			
Operation	src .XOR. dst → dst				
Description	The source and destination operands are exclusive ORed. The result is placed into the destination. The source operand is not affected.				
Status Bits	N: Set if result MSB is set, reset if not set Z: Set if result is zero, reset otherwise C: Set if result is not zero, reset otherwise (= .NOT. Zero) V: Set if both operands are negative				
Mode Bits	OSCOFF, CPUOFF, and GIE are not affected.				
Example	The bits set in R6 toggle the bits in the RAM word TONI.				
	XOR	R6,TONI	; Toggle bits of word TONI on the bits set in R6		
Example	The bits set in R6 toggle the bits in the RAM byte TONI.				
	XOR.B	R6,TONI	; Toggle bits of byte TONI on the bits set in ; low byte of R6		
Example	Reset to 0 those bits in low byte of R7 that are different from bits in RAM byte EDE.				
	XOR.B	EDE,R7	; Set different bit to “1s”		
	INV.B	R7	; Invert Lowbyte, Highbyte is 0h		

3.4.4 Instruction Cycles and Lengths

The number of CPU clock cycles required for an instruction depends on the instruction format and the addressing modes used - not the instruction itself. The number of clock cycles refers to the MCLK.

Interrupt and Reset Cycles

Table 3–14 lists the CPU cycles for interrupt overhead and reset.

Table 3–14. Interrupt and Reset Cycles

Action	No. of Cycles	Length of Instruction
Return from interrupt (RETI)	5	1
Interrupt accepted	6	–
WDT reset	4	–
Reset ($\overline{\text{RST}}$ /NMI)	4	–

Format-II (Single Operand) Instruction Cycles and Lengths

Table 3–15 lists the length and CPU cycles for all addressing modes of format-II instructions.

Table 3–15. Format-II Instruction Cycles and Lengths

Addressing Mode	No. of Cycles			Length of Instruction	Example
	RRA, RRC SWPB, SXT	PUSH	CALL		
Rn	1	3	4	1	SWPB R5
@Rn	3	4	4	1	RRC @R9
@Rn+	3	5	5	1	SWPB @R10+
#N	(See note)	4	5	2	CALL #0F000h
X(Rn)	4	5	5	2	CALL 2 (R7)
EDE	4	5	5	2	PUSH EDE
&EDE	4	5	5	2	SXT &EDE

Note: Instruction Format II Immediate Mode

Do not use instructions RRA, RRC, SWPB, and SXT with the immediate mode in the destination field. Use of these in the immediate mode results in an unpredictable program operation.

Format-III (Jump) Instruction Cycles and Lengths

All jump instructions require one code word, and take two CPU cycles to execute, regardless of whether the jump is taken or not.

Format-I (Double Operand) Instruction Cycles and Lengths

Table 3–16 lists the length and CPU cycles for all addressing modes of format-I instructions.

Table 3–16.Format 1 Instruction Cycles and Lengths

Addressing Mode		No. of Cycles	Length of Instruction		Example
Src	Dst				
Rn	Rm	1	1	MOV	R5, R8
	PC	2	1	BR	R9
	x(Rm)	4	2	ADD	R5, 4 (R6)
	EDE	4	2	XOR	R8, EDE
	&EDE	4	2	MOV	R5, &EDE
@Rn	Rm	2	1	AND	@R4, R5
	PC	2	1	BR	@R8
	x(Rm)	5	2	XOR	@R5, 8 (R6)
	EDE	5	2	MOV	@R5, EDE
	&EDE	5	2	XOR	@R5, &EDE
@Rn+	Rm	2	1	ADD	@R5+, R6
	PC	3	1	BR	@R9+
	x(Rm)	5	2	XOR	@R5, 8 (R6)
	EDE	5	2	MOV	@R9+, EDE
	&EDE	5	2	MOV	@R9+, &EDE
#N	Rm	2	2	MOV	#20, R9
	PC	3	2	BR	#2AEh
	x(Rm)	5	3	MOV	#0300h, 0 (SP)
	EDE	5	3	ADD	#33, EDE
	&EDE	5	3	ADD	#33, &EDE
x(Rn)	Rm	3	2	MOV	2 (R5), R7
	PC	3	2	BR	2 (R6)
	TONI	6	3	MOV	4 (R7), TONI
	x(Rm)	6	3	ADD	4 (R4), 6 (R9)
	&TONI	6	3	MOV	2 (R4), &TONI
EDE	Rm	3	2	AND	EDE, R6
	PC	3	2	BR	EDE
	TONI	6	3	CMP	EDE, TONI
	x(Rm)	6	3	MOV	EDE, 0 (SP)
	&TONI	6	3	MOV	EDE, &TONI
&EDE	Rm	3	2	MOV	&EDE, R8
	PC	3	2	BRA	&EDE
	TONI	6	3	MOV	&EDE, TONI
	x(Rm)	6	3	MOV	&EDE, 0 (SP)
	&TONI	6	3	MOV	&EDE, &TONI

3.4.5 Instruction Set Description

The instruction map is shown in Figure 3–20 and the complete instruction set is summarized in Table 3–17.

Figure 3–20. Core Instruction Map

	000	040	080	0C0	100	140	180	1C0	200	240	280	2C0	300	340	380	3C0

† Emulated Instruction

Basic Clock Module+

The basic clock module+ provides the clocks for MSP430x2xx devices. This chapter describes the operation of the basic clock module+ of the MSP430x2xx device family.

Topic	Page
4.1 Basic Clock Module+ Introduction	4-2
4.2 Basic Clock Module+ Operation	4-4
4.3 Basic Clock Module+ Registers	4-13

4.1 Basic Clock Module+ Introduction

The basic clock module+ supports low system cost and ultralow-power consumption. Using three internal clock signals, the user can select the best balance of performance and low power consumption. The basic clock module+ can be configured to operate without any external components, with one external resistor, with one or two external crystals, or with resonators, under full software control.

The basic clock module+ includes three or four clock sources:

- ☐ LFXT1CLK: Low-frequency/high-frequency oscillator that can be used with low-frequency watch crystals or external clock sources of 32,768 Hz, or with standard crystals, resonators, or external clock sources in the 400-kHz to 16-MHz range.
- ☐ XT2CLK: Optional high-frequency oscillator that can be used with standard crystals, resonators, or external clock sources in the 400-kHz to 16-MHz range.
- ☐ DCOCLK: Internal digitally controlled oscillator (DCO).
- ☐ VLOCLK: Internal very low power, low frequency oscillator with 12-kHz typical frequency.

Three clock signals are available from the basic clock module+:

- ☐ ACLK: Auxiliary clock. ACLK is software selectable as LFXT1CLK or VLOCLK. ACLK is divided by 1, 2, 4, or 8. ACLK is software selectable for individual peripheral modules.
- ☐ MCLK: Master clock. MCLK is software selectable as LFXT1CLK, VLOCLK, XT2CLK (if available on-chip), or DCOCLK. MCLK is divided by 1, 2, 4, or 8. MCLK is used by the CPU and system.
- ☐ SMCLK: Sub-main clock. SMCLK is software selectable as LFXT1CLK, VLOCLK, XT2CLK (if available on-chip), or DCOCLK. SMCLK is divided by 1, 2, 4, or 8. SMCLK is software selectable for individual peripheral modules.

The block diagram of the basic clock module+ is shown in Figure 4–1.

Note: Device-Specific Clock Variations

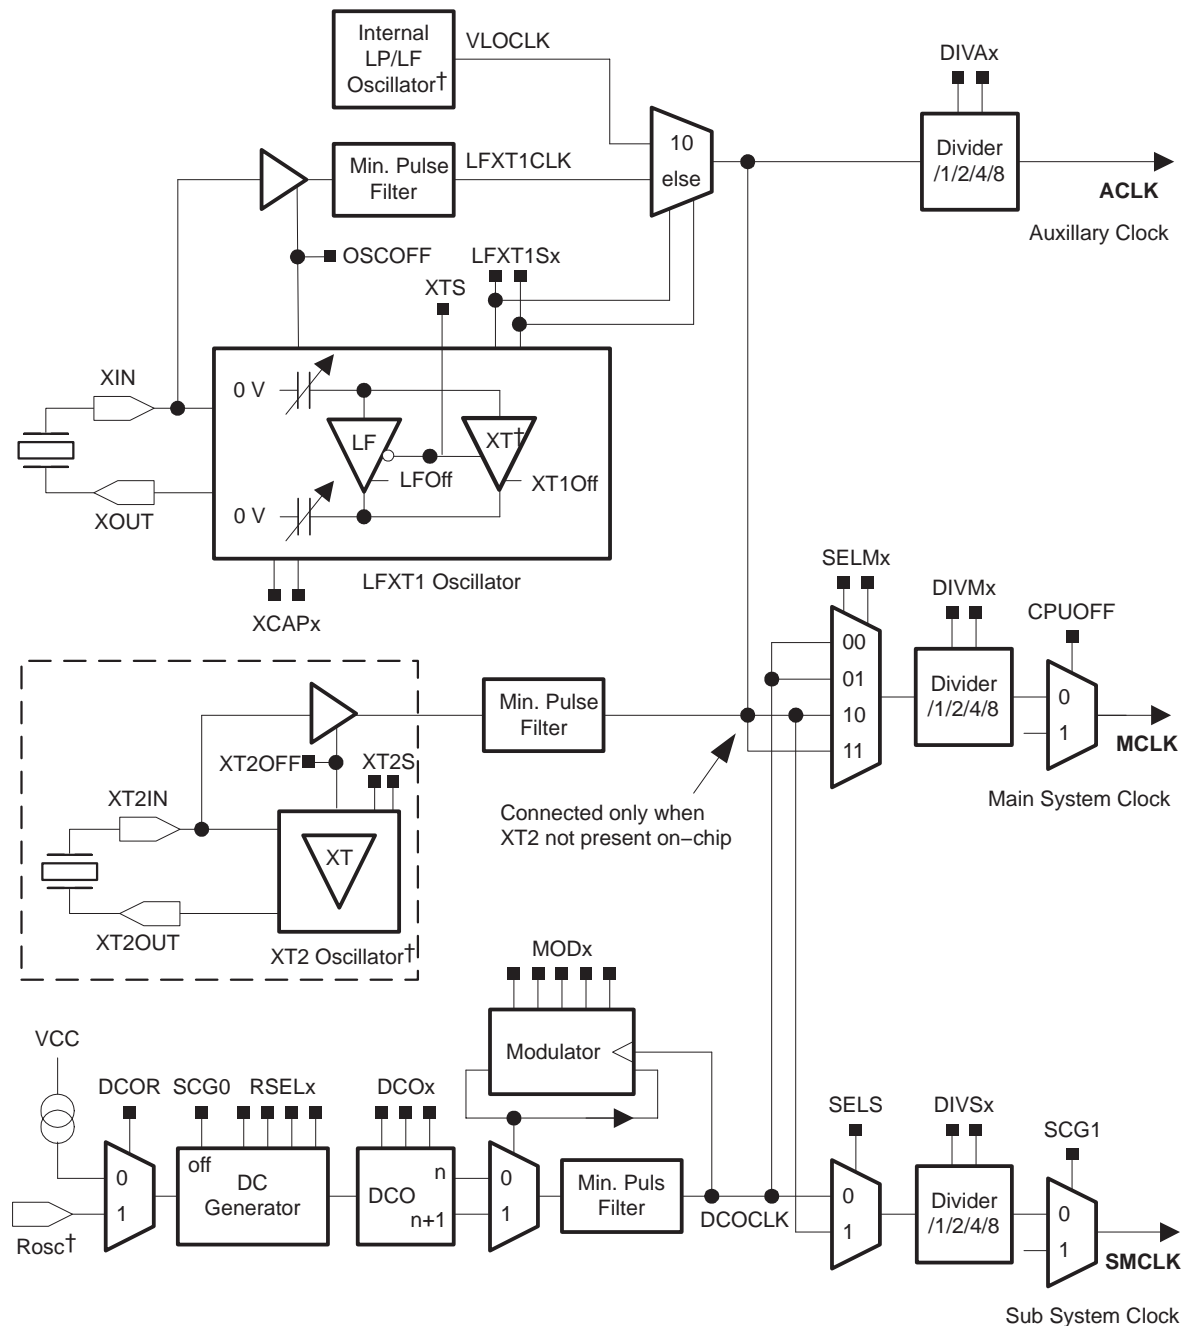

All clock features are not available on all MSP430x2xx devices.

MSP430x20xx: LFXT1 does not support HF mode, XT2 is not present, R_{OSC} is not supported.

MSP430x21xx: Internal LP/LF oscillator is not present, XT2 is not present, R_{OSC} is not supported.

MSP430x22xx, MSP430x23x0: XT2 is not present.

Figure 4–1. Basic Clock Module+ Block Diagram

**†Note: Device-Specific Clock Variations**

All clock features are not available on all MSP430x2xx devices.

MSP430x20xx: LFXT1 does not support HF mode, XT2 is not present, R_{OSC} is not supported.

MSP430x21xx: Internal LP/LF oscillator is not present, XT2 is not present, R_{OSC} is not supported.

MSP430x22xx, MSP430x23x0: XT2 is not present.

4.2 Basic Clock Module+ Operation

After a PUC, MCLK and SMCLK are sourced from DCOCLK at ~1.1 MHz (see device-specific datasheet for parameters), and ACLK is sourced from LFXT1CLK in LF mode with an internal load capacitance of 6 pF.

Status register control bits SCG0, SCG1, OSCOFF, and CPUOFF configure the MSP430 operating modes and enable or disable portions of the basic clock module+. See Chapter *System Resets, Interrupts and Operating Modes*. The DCOCTL, BCSCTL1, BCSCTL2, and BCSCTL3 registers configure the basic clock module+.

The basic clock module+ can be configured or reconfigured by software at any time during program execution, for example:

```
BIS.B #RSEL2+RSEL1+RSEL0,&BCSCTL1 ; Select range 7
BIS.B #DCO2+DCO1+DCO0,&DCOCTL    ; Select max DCO tap
```

4.2.1 Basic Clock Module+ Features for Low-Power Applications

Conflicting requirements typically exist in battery-powered applications:

- ☐ Low clock frequency for energy conservation and time keeping
- ☐ High clock frequency for fast reaction to events and fast burst processing capability
- ☐ Clock stability over operating temperature and supply voltage

The basic clock module+ addresses the above conflicting requirements by allowing the user to select from the three available clock signals: ACLK, MCLK, and SMCLK. For optimal low-power performance, ACLK can be sourced from a low-power 32,768-Hz watch crystal, providing a stable time base for the system and low power stand-by operation, or from the internal low-frequency oscillator when crystal-accurate time keeping is not required.. The MCLK can be configured to operate from the on-chip DCO that can be activated when requested by interrupt-driven events. The SMCLK can be configured to operate from a crystal or the DCO, depending on peripheral requirements. A flexible clock distribution and divider system is provided to fine tune the individual clock requirements.

4.2.2 Internal Very Low Power, Low Frequency Oscillator

The internal very-low-power, low-frequency oscillator (VLO) provides a typical frequency of 12kHz (see device-specific datasheet for parameters) without requiring a crystal. VLOCLK source is selected by setting LFXT1Sx = 10 when XTS = 0. The OSCOFF bit disables the VLO for LPM4. The LFXT1 crystal oscillators are disabled when the VLO is selected reducing current consumption. The VLO consumes no power when not being used.

4.2.3 LFXT1 Oscillator

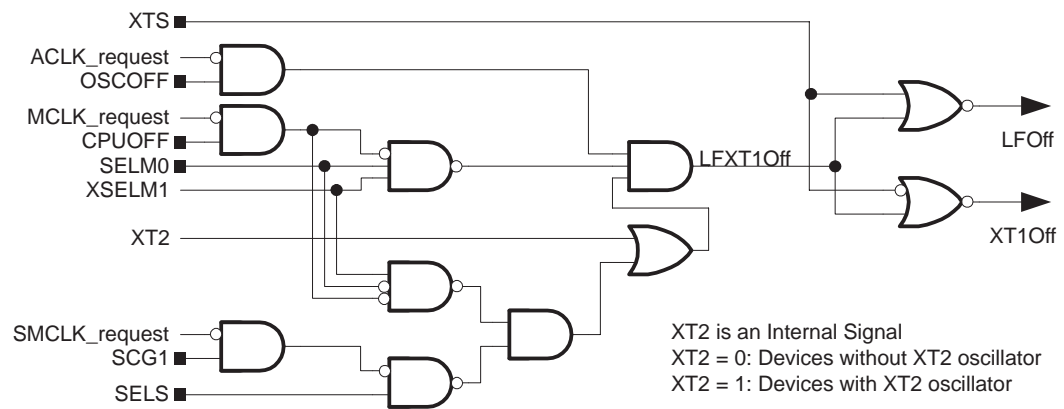

The LFXT1 oscillator supports ultralow-current consumption using a 32,768-Hz watch crystal in LF mode (XTS = 0). A watch crystal connects to XIN and XOUT without any other external components. The software-selectable XCAPx bits configure the internally provided load capacitance for the LFXT1 crystal in LF mode. This capacitance can be selected as 1pF, 6pF, 10pF or 12.5pF typical. Additional external capacitors can be added if necessary.

The LFXT1 oscillator also supports high-speed crystals or resonators when in HF mode (XTS = 1, XCAPx = 00). The high-speed crystal or resonator connects to XIN and XOUT and requires external capacitors on both terminals. These capacitors should be sized according to the crystal or resonator specifications. When LFXT1 is in HF mode, the LFXT1Sx bits select the range of operation.

LFXT1 may be used with an external clock signal on the XIN pin in either LF or HF mode when LFXT1Sx = 11, OSCOFF = 0 and XCAPx = 00. When used with an external signal, the external frequency must meet the datasheet parameters for the chosen mode. When the input frequency is below the specified lower limit, the LFXT1OF bit may be set preventing the CPU from being clocked with LFXT1CLK.

Software can disable LFXT1 by setting OSCOFF, if LFXT1CLK does not source SMCLK or MCLK, as shown in Figure 4–2.

Figure 4–2. Off Signals for the LFXT1 Oscillator

Note: LFXT1 Oscillator Characteristics

Low-frequency crystals often require hundreds of milliseconds to start up, depending on the crystal.

Ultralow-power oscillators such as the LFXT1 in LF mode should be guarded from noise coupling from other sources. The crystal should be placed as close as possible to the MSP430 with the crystal housing grounded and the crystal traces guarded with ground traces.

4.2.4 XT2 Oscillator

Some devices have a second crystal oscillator, XT2. XT2 sources XT2CLK and its characteristics are identical to LFXT1 in HF mode. The XT2Sx bits select the range of operation of XT2. The XT2OFF bit disables the XT2 oscillator if XT2CLK is not used for MCLK or SMCLK as shown in Figure 4–3.

XT2 may be used with external clock signals on the XT2IN pin when XT2Sx = 11 and XT2OFF = 0. When used with an external signal, the external frequency must meet the datasheet parameters for XT2. When the input frequency is below the specified lower limit, the XT2OF bit may be set preventing the CPU from being clocked with XT2CLK.

Figure 4–3. Off Signals for Oscillator XT2

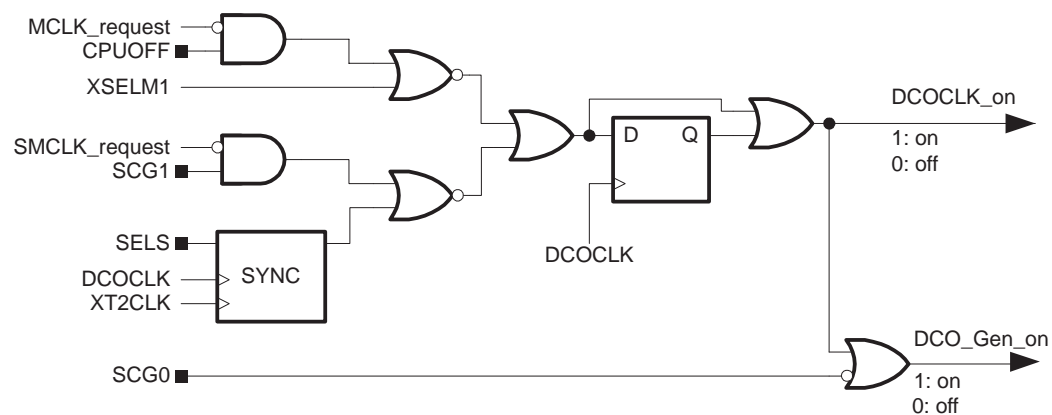

4.2.5 Digitally-Controlled Oscillator (DCO)

The DCO is an integrated digitally controlled oscillator. The DCO frequency can be adjusted by software using the DCOx, MODx, and RSELx bits.

Disabling the DCO

Software can disable DCOCLK by setting SCG0 when it is not used to source SMCLK or MCLK in active mode, as shown in Figure 4–4.

Figure 4–4. On/Off Control of DCO

Adjusting the DCO frequency

After a PUC, $RSELx = 7$ and $DCOx = 3$, allowing the DCO to start at a mid-range frequency. MCLK and SMCLK are sourced from DCOCLK. Because the CPU executes code from MCLK, which is sourced from the fast-starting DCO, code execution typically begins from PUC in less than 2 μ s. The typical $DCOx$ and $RSELx$ ranges and steps are shown in Figure 4–5.

The frequency of DCOCLK is set by the following functions:

- ☐ The four $RSELx$ bits select one of sixteen nominal frequency ranges for the DCO. These ranges are defined for an individual device in the device-specific data sheet.
- ☐ The three $DCOx$ bits divide the DCO range selected by the $RSELx$ bits into 8 frequency steps, separated by approximately 10%.
- ☐ The five $MODx$ bits, switch between the frequency selected by the $DCOx$ bits and the next higher frequency set by $DCOx+1$. When $DCOx = 07h$, the $MODx$ bits have no effect because the DCO is already at the highest setting for the selected $RSELx$ range.

Figure 4–5. Typical $DCOx$ Range and $RSELx$ Steps

Each MSP430F2xx device has calibrated DCOCTL and BCSCTL1 register settings for specific frequencies stored in information memory segment A. To use the calibrated settings, the information is copied into the DCOCTL and BCSCTL1 registers. The calibrated settings affect the DCOx, MODx, and RSELx bits, and clear all other bits, except XT2OFF which remains set. The remaining bits of BCSCTL1 can be set or cleared as needed with `BIS.B` or `BIC.B` instructions.

```
; Set DCO to 1 MHz:
MOV.B  &CALBC1_1MHZ,&BCSCTL1 ; Set range
MOV.B  &CALDCO_1MHZ,&DCOCTL   ; Set DCO step + modulation
```

Using an External Resistor (R_{OSC}) for the DCO

Some MSP430F2xx devices provide the option to source the DCO current through an external resistor, R_{OSC} , tied to DV_{CC} , when $DCOR = 1$. In this case, the DCO has the same characteristics as MSP430x1xx devices, and the RSELx setting is limited to 0 to 7 with the RSEL3 ignored. This option provides an additional method to tune the DCO frequency by varying the resistor value. See the device-specific datasheet for parameters.

4.2.6 DCO Modulator

The modulator mixes two DCO frequencies, f_{DCO} and $f_{\text{DCO}+1}$ to produce an intermediate effective frequency between f_{DCO} and $f_{\text{DCO}+1}$ and spread the clock energy, reducing electromagnetic interference (EMI). The modulator mixes f_{DCO} and $f_{\text{DCO}+1}$ for 32 DCOCLK clock cycles and is configured with the MODx bits. When MODx = 0 the modulator is off.

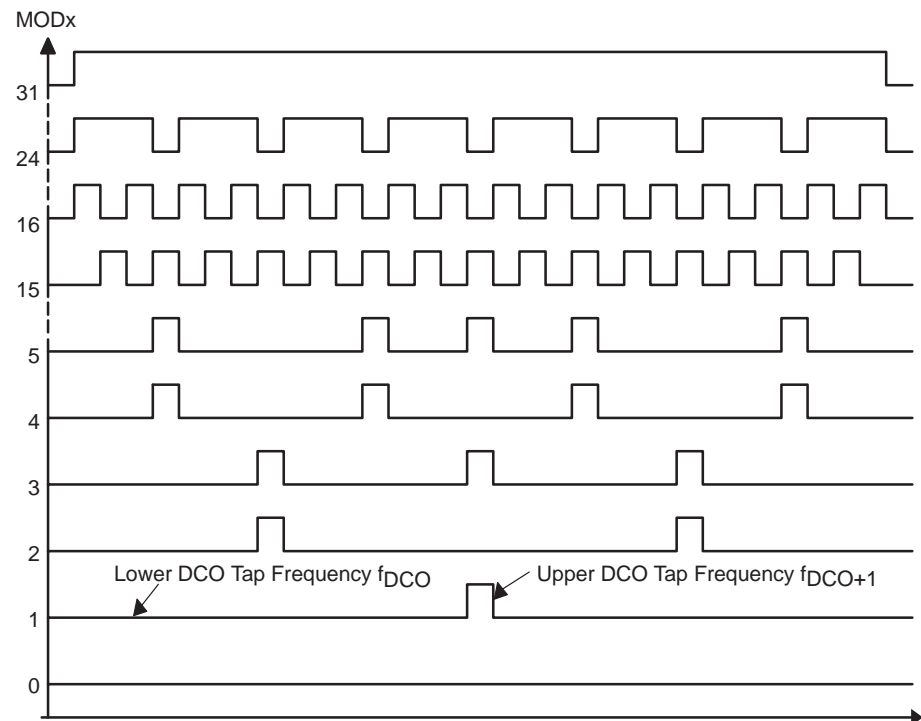

The modulator mixing formula is:

$$t = (32 - \text{MODx}) \times t_{\text{DCO}} + \text{MODx} \times t_{\text{DCO}+1}$$

Because f_{DCO} is lower than the effective frequency and $f_{\text{DCO}+1}$ is higher than the effective frequency, the error of the effective frequency integrates to zero. It does not accumulate. The error of the effective frequency is zero every 32 DCOCLK cycles. Figure 4–6 illustrates the modulator operation.

The modulator settings and DCO control are configured with software. The DCOCLK can be compared to a stable frequency of known value and adjusted with the DCOx, RSELx, and MODx bits. See <http://www.msp430.com> for application notes and example code on configuring the DCO.

Figure 4–6. Modulator Patterns

4.2.7 Basic Clock Module+ Fail-Safe Operation

The basic clock module+ incorporates an oscillator-fault fail-safe feature. This feature detects an oscillator fault for LFXT1 and XT2 as shown in Figure 4–7. The available fault conditions are:

- ❑ Low-frequency oscillator fault (LFXT1OF) for LFXT1 in LF mode
- ❑ High-frequency oscillator fault (LFXT1OF) for LFXT1 in HF mode
- ❑ High-frequency oscillator fault (XT2OF) for XT2

The crystal oscillator fault bits LFXT1OF, and XT2OF are set if the corresponding crystal oscillator is turned on and not operating properly. The fault bits remain set as long as the fault condition exists and are automatically cleared if the enabled oscillators function normally.

The OFIFG oscillator-fault flag is set and latched at POR or when an oscillator fault (LFXT1OF, or XT2OF) is detected. When OFIFG is set, MCLK is sourced from the DCO, and if OFIE is set, the OFIFG requests an NMI interrupt. When the interrupt is granted, the OFIE is reset automatically. The OFIFG flag must be cleared by software. The source of the fault can be identified by checking the individual fault bits.

If a fault is detected for the crystal oscillator sourcing the MCLK, the MCLK is automatically switched to the DCO for its clock source. This does not change the SELMx bit settings. This condition must be handled by user software.

Figure 4–7. Oscillator-Fault Logic

Sourcing MCLK from a Crystal

After a PUC, the basic clock module+ uses DCOCLK for MCLK. If required, MCLK may be sourced from LFXT1 or XT2.

The sequence to switch the MCLK source from the DCO clock to the crystal clock (LFXT1CLK or XT2CLK) is:

- 1) Switch on the crystal oscillator and select appropriate mode
- 2) Clear the OFIFG flag
- 3) Wait at least 50 μ s
- 4) Test OFIFG, and repeat steps 1-4 until OFIFG remains cleared.

```
; Select LFXT1 (HF mode) for MCLK
    BIC.W #OSCOFF,SR           ; Turn on osc.
    BIS.B #XTS,&BCSCTL1        ; HF mode
    MOV.B #LFXT1S0,&BCSCTL3     ; 1-3MHz Crystal
L1 BIC.B #OFIFG,&IFG1           ; Clear OFIFG
    MOV.W #0FFh,R15            ; Delay
L2 DEC.W R15                    ;
    JNZ    L2                  ;
    BIT.B #OFIFG,&IFG1          ; Re-test OFIFG
    JNZ    L1                  ; Repeat test if needed
    BIS.B #SELM1+SELM0,&BCSCTL2 ; Select LFXT1CLK
```

4.2.8 Synchronization of Clock Signals

When switching MCLK or SMCLK from one clock source to the other, the switch is synchronized to avoid critical race conditions as shown in Figure 4–8:

- 1) The current clock cycle continues until the next rising edge.
- 2) The clock remains high until the next rising edge of the new clock.
- 3) The new clock source is selected and continues with a full high period.

Figure 4–8. Switch MCLK from DCOCLK to LFXT1CLK

4.3 Basic Clock Module+ Registers

The basic clock module+ registers are listed in Table 4–1:

Table 4–1. Basic Clock module+ Registers

Register	Short Form	Register Type	Address	Initial State
DCO control register	DCOCTL	Read/write	056h	060h with PUC
Basic clock system control 1	BCSCTL1	Read/write	057h	087h with POR
Basic clock system control 2	BCSCTL2	Read/write	058h	Reset with PUC
Basic clock system control 3	BCSCTL3	Read/write	053h	005h with PUC
SFR interrupt enable register 1	IE1	Read/write	000h	Reset with PUC
SFR interrupt flag register 1	IFG1	Read/write	002h	Reset with PUC

DCOCTL, DCO Control Register

DCOx	Bits 7-5	DCO frequency select. These bits select which of the eight discrete DCO frequencies within the range defined by the RSELx setting is selected.
MODx	Bits 4-0	Modulator selection. These bits define how often the $f_{\text{DCO}+1}$ frequency is used within a period of 32 DCOCLK cycles. During the remaining clock cycles (32-MOD) the f_{DCO} frequency is used. Not useable when DCOx=7.

BCSCTL1, Basic Clock System Control Register 1

XT2OFF	Bit 7	XT2 off. This bit turns off the XT2 oscillator 0 XT2 is on 1 XT2 is off if it is not used for MCLK or SMCLK.
XTS	Bit 6	LFXT1 mode select. 0 Low frequency mode 1 High frequency mode
DIVAx	Bits 5-4	Divider for ACLK 00 /1 01 /2 10 /4 11 /8
RSELx	Bits 3-0	Range Select. Sixteen different frequency ranges are available. The lowest frequency range is selected by setting RSELx=0. RSEL3 is ignored when DCOR = 1.

BCSCTL2, Basic Clock System Control Register 2

7	6	5	4	3	2	1	0
SELMx		DIVMx		SELS	DIVSx		DCOR†
rw-0		rw-0		rw-0	rw-0		rw-0

† Does not apply to MSP430x20xx or MSP430x21xx.

SELMx	Bits	Select MCLK. These bits select the MCLK source.	
	7-6	00	DCOCLK
		01	DCOCLK
		10	XT2CLK when XT2 oscillator present on-chip. LFXT1CLK or VLOCLK when XT2 oscillator not present on-chip.
		11	LFXT1CLK or VLOCLK
DIVMx	BitS	Divider for MCLK	
	5-4	00	/1
		01	/2
		10	/4
		11	/8
SELS	Bit 3	Select SMCLK. This bit selects the SMCLK source.	
		0	DCOCLK
		1	XT2CLK when XT2 oscillator present. LFXT1CLK or VLOCLK when XT2 oscillator not present
DIVSx	BitS	Divider for SMCLK	
	2-1	00	/1
		01	/2
		10	/4
		11	/8
DCOR	Bit 0	DCO resistor select	
		0	Internal resistor
		1	External resistor

BCSCTL3, Basic Clock System Control Register 3

7	6	5	4	3	2	1	0
XT2Sx		LFXT1Sx		XCAPx		XT2OF†	LFXT1OF
rw-0		rw-0		rw-0		r0	r-(1)

† Does not apply to MSP430x2xx, MSP430x21xx, or MSP430x22xx devices

XT2Sx	Bits 7-6	XT2 range select. These bits select the frequency range for XT2. 00 0.4 – 1MHz crystal or resonator 01 1 – 3MHz crystal or resonator 10 3 – 16MHz crystal or resonator 11 Digital external 0.4 – 16MHz clock source
LFXT1Sx	Bits 5-4	Low-frequency clock select and LFXT1 range select. These bits select between LFXT1 and VLO when XTS = 0, and select the frequency range for LFXT1 when XTS = 1. When XTS = 0: 00 32768 Hz Crystal on LFXT1 01 Reserved 10 VLOCLK (Reserved in MSP430x21x1 devices) 11 Digital external clock source When XTS = 1 (Not applicable for MSP430x20xx devices) 00 0.4 – 1MHz crystal or resonator 01 1 – 3MHz crystal or resonator 10 3 – 16MHz crystal or resonator 11 Digital external 0.4 – 16MHz clock source
XCAPx	Bits 3-2	Oscillator capacitor selection. These bits select the effective capacitance seen by the LFXT1 crystal when XTS = 0. If XTS = 1 or if LFXT1Sx = 11 XCAPx should be 00. 00 ~1pF 01 ~6pF 10 ~10pF 11 ~12.5pF

IE1, Interrupt Enable Register 1

	Bits 7-2	These bits may be used by other modules. See device-specific datasheet.
OFIE	Bit 1	<p>Oscillator fault interrupt enable. This bit enables the OFIFG interrupt. Because other bits in IE1 may be used for other modules, it is recommended to set or clear this bit using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions.</p> <p>0 Interrupt not enabled</p> <p>1 Interrupt enabled</p>
	Bits 0	This bit may be used by other modules. See device-specific datasheet.

IFG1, Interrupt Flag Register 1

	Bits 7-2	These bits may be used by other modules. See device-specific datasheet.
OFIFG	Bit 1	<p>Oscillator fault interrupt flag. Because other bits in IFG1 may be used for other modules, it is recommended to set or clear this bit using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions.</p> <p>0 No interrupt pending</p> <p>1 Interrupt pending</p>
	Bits 0	This bit may be used by other modules. See device-specific datasheet.

Flash Memory Controller

This chapter describes the operation of the MSP430x2xx flash memory controller.

Topic	Page
5.1 Flash Memory Introduction	5-2
5.2 Flash Memory Segmentation	5-3
5.3 Flash Memory Operation	5-5
5.4 Flash Memory Registers	5-19

5.1 Flash Memory Introduction

The MSP430 flash memory is bit-, byte-, and word-addressable and programmable. The flash memory module has an integrated controller that controls programming and erase operations. The controller has three registers, a timing generator, and a voltage generator to supply program and erase voltages.

MSP430 flash memory features include:

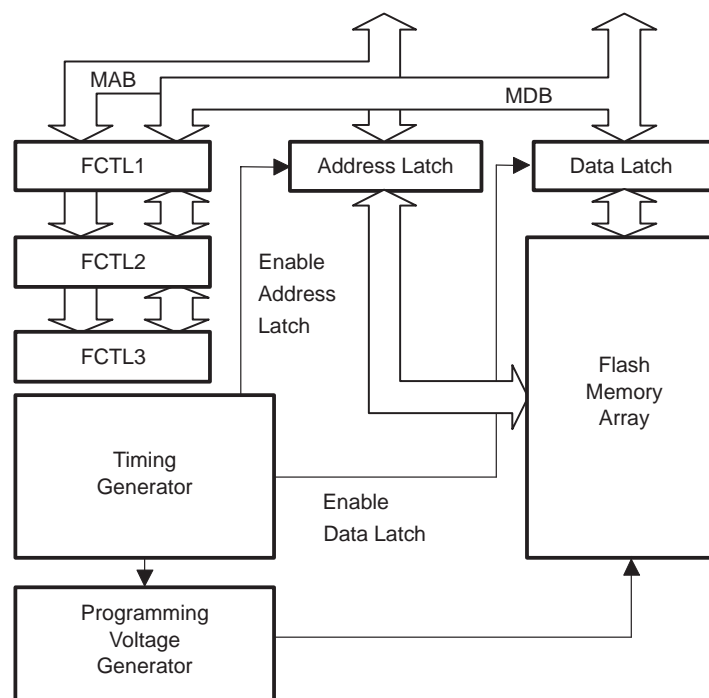

- ☐ Internal programming voltage generation
- ☐ Bit, byte or word programmable
- ☐ Ultralow-power operation
- ☐ Segment erase and mass erase

The block diagram of the flash memory and controller is shown in Figure 5–1.

Note: Minimum V_{CC} During Flash Write or Erase

The minimum V_{CC} voltage during a flash write or erase operation is 2.2 V. If V_{CC} falls below 2.2 V during a write or erase, the result of the write or erase will be unpredictable.

Figure 5–1. Flash Memory Module Block Diagram

5.2 Flash Memory Segmentation

MSP430 flash memory is partitioned into segments. Single bits, bytes, or words can be written to flash memory, but the segment is the smallest size of flash memory that can be erased.

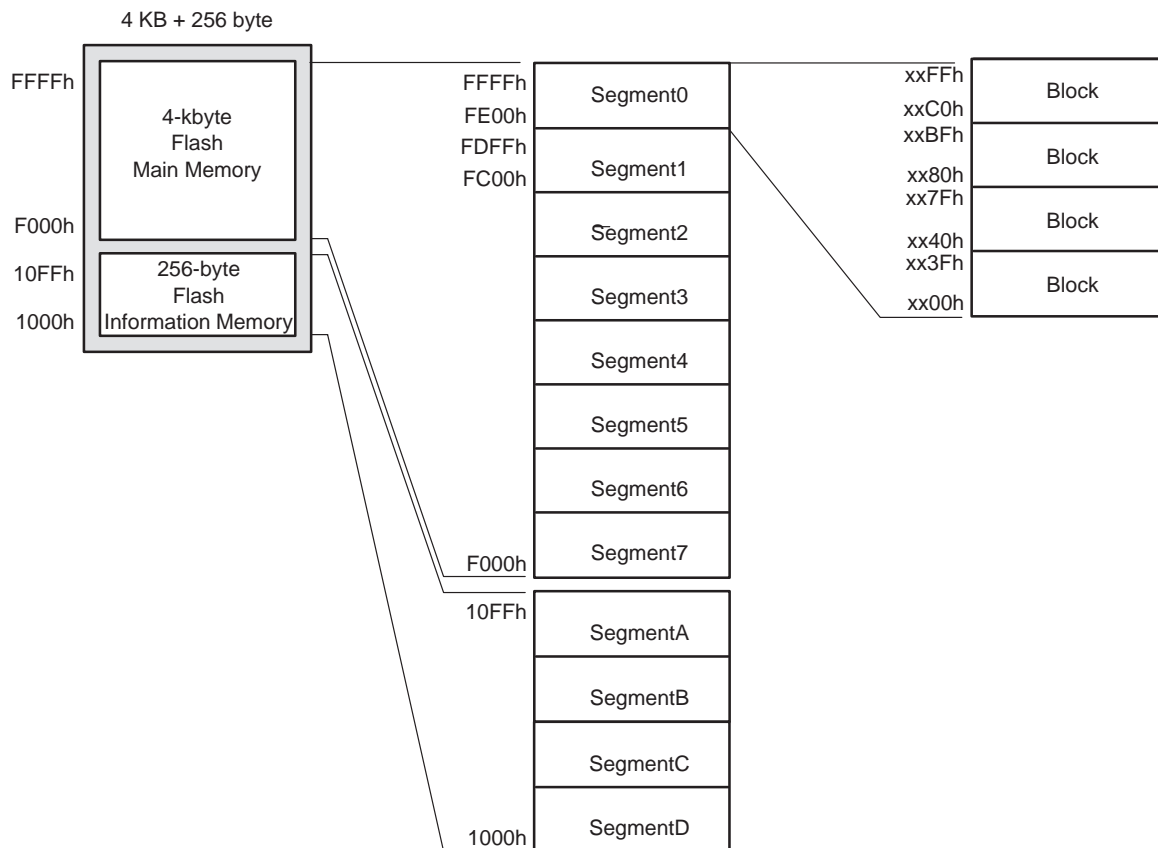

The flash memory is partitioned into main and information memory sections. There is no difference in the operation of the main and information memory sections. Code or data can be located in either section. The differences between the two sections are the segment size and the physical addresses.

The information memory has four 64-byte segments. The main memory has two or more 512-byte segments. See the device-specific datasheet for the complete memory map of a device.

The segments are further divided into blocks. A block is 64 bytes, starting at 0xx00h, 0xx40h, 0xx80h, or 0xxC0h, and ending at 0xx3Fh, 0xx7Fh, 0xxBFh, or 0xFFh.

Figure 5–2 shows the flash segmentation using an example of 4-KB flash that has eight main segments and four information segments.

Figure 5–2. Flash Memory Segments, 4-KB Example

5.2.1 SegmentA

SegmentA of the information memory is locked separately from all other segments with the LOCKA bit. When LOCKA = 1, SegmentA cannot be written or erased and all information memory is protected from erasure during a mass erase. When LOCKA = 0, SegmentA can be erased and written as any other flash memory segment, and all information memory is erased during a mass erase. Segments B, C, and D can always be erased with a segment erase, regardless of the state of the LOCKA bit.

The state of the LOCKA bit is toggled when a 1 is written to it. Writing a 0 to LOCKA has no affect. This allows existing flash programming routines to be used unchanged.

```
; Unlock SegmentA
    BIT    #LOCKA,&FCTL3           ; Test LOCKA
    JZ     SEGA_UNLOCKED           ; Already unlocked?
    MOV    #FWKEY+LOCKA,&FCTL3     ; No, unlock SegmentA
SEGA_UNLOCKED                       ; Yes, continue
; SegmentA is unlocked

; Lock SegmentA
    BIT    #LOCKA,&FCTL3           ; Test LOCKA
    JNZ    SEGALOCKED              ; Already locked?
    MOV    #FWKEY+LOCKA,&FCTL3     ; No, lock SegmentA
SEGA_LOCKED                         ; Yes, continue
; SegmentA is locked
```

5.3 Flash Memory Operation

The default mode of the flash memory is read mode. In read mode, the flash memory is not being erased or written, the flash timing generator and voltage generator are off, and the memory operates identically to ROM.

MSP430 flash memory is in-system programmable (ISP) without the need for additional external voltage. The CPU can program its own flash memory. The flash memory write/erase modes are selected with the BLKWRT, WRT, MERAS, and ERASE bits and are:

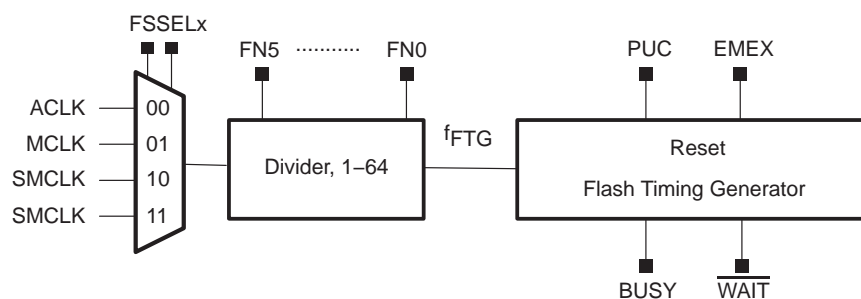

- ☐ Byte/word write
- ☐ Block write
- ☐ Segment Erase
- ☐ Mass Erase (all main memory segments)
- ☐ All Erase (all segments)

Reading or writing to flash memory while it is being programmed or erased is prohibited. If CPU execution is required during the write or erase, the code to be executed must be in RAM. Any flash update can be initiated from within flash memory or RAM.

5.3.1 Flash Memory Timing Generator

Write and erase operations are controlled by the flash timing generator shown in Figure 5–3. The flash timing generator operating frequency, f_{FTG} , must be in the range from ~ 257 kHz to ~ 476 kHz (see device-specific datasheet).

Figure 5–3. Flash Memory Timing Generator Block Diagram

Flash Timing Generator Clock Selection

The flash timing generator can be sourced from ACLK, SMCLK, or MCLK. The selected clock source should be divided using the FNx bits to meet the frequency requirements for f_{FTG} . If the f_{FTG} frequency deviates from the specification during the write or erase operation, the result of the write or erase may be unpredictable, or the flash memory may be stressed above the limits of reliable operation.

If a clock failure is detected during a write or erase operation, the operation is aborted, the FAIL flag is set, and the result of the operation is unpredictable.

While a write or erase operation is active the selected clock source can not be disabled by putting the MSP430 into a low-power mode. The selected clock source will remain active until the operation is completed before being disabled.

5.3.2 Erasing Flash Memory

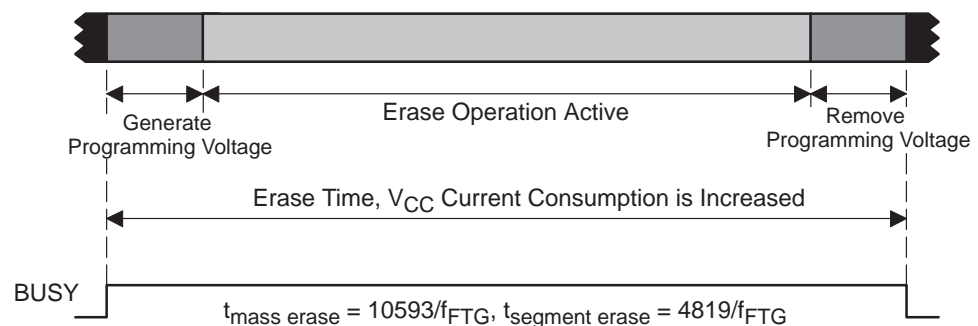

The erased level of a flash memory bit is 1. Each bit can be programmed from 1 to 0 individually but to reprogram from 0 to 1 requires an erase cycle. The smallest amount of flash that can be erased is a segment. There are three erase modes selected with the ERASE and MERAS bits listed in Table 5–1.

Table 5–1. Erase Modes

MERAS	ERASE	Erase Mode
0	1	Segment erase
1	0	Mass erase (all main memory segments)
1	1	Erase all flash memory (main and information segments) if LOCKA = 0. Main segments only if LOCKA = 1.

Any erase is initiated by a dummy write into the address range to be erased. The dummy write starts the flash timing generator and the erase operation. Figure 5–4 shows the erase cycle timing. The BUSY bit is set immediately after the dummy write and remains set throughout the erase cycle. BUSY, MERAS, and ERASE are automatically cleared when the cycle completes. The erase cycle timing is not dependent on the amount of flash memory present on a device. Erase cycle times are equivalent for all MSP430F2xx devices.

Figure 5–4. Erase Cycle Timing

A dummy write to an address not in the range to be erased does not start the erase cycle, does not affect the flash memory, and is not flagged in any way. This errant dummy write is ignored.

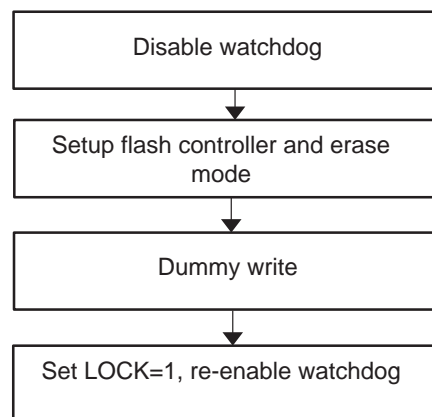

Initiating an Erase from Within Flash Memory

Any erase cycle can be initiated from within flash memory or from RAM. When a flash segment erase operation is initiated from within flash memory, all timing is controlled by the flash controller, and the CPU is held while the erase cycle completes. After the erase cycle completes, the CPU resumes code execution with the instruction following the dummy write.

When initiating an erase cycle from within flash memory, it is possible to erase the code needed for execution after the erase. If this occurs, CPU execution will be unpredictable after the erase cycle.

The flow to initiate an erase from flash is shown in Figure 5–5.

Figure 5–5. Erase Cycle from Within Flash Memory

```

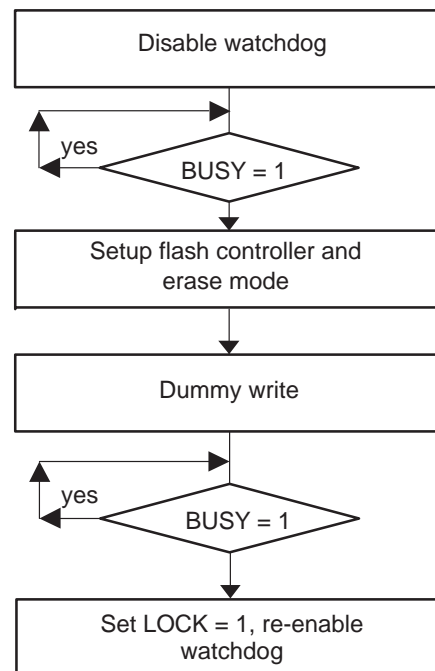

; Segment Erase from flash. 514 kHz < SMCLK < 952 kHz
; Assumes ACCVIE = NMIE = OFIE = 0.
MOV    #WDTPW+WDTHOLD,&WDTCTL    ; Disable WDT
MOV    #FWKEY+FSSEL1+FN0,&FCTL2   ; SMCLK/2
MOV    #FWKEY,&FCTL3              ; Clear LOCK
MOV    #FWKEY+ERASE,&FCTL1        ; Enable segment erase
CLR    &0FC10h                   ; Dummy write, erase S1
MOV    #FWKEY+LOCK,&FCTL3         ; Done, set LOCK
...
; Re-enable WDT?
  
```

Initiating an Erase from RAM

Any erase cycle may be initiated from RAM. In this case, the CPU is not held and can continue to execute code from RAM. The BUSY bit must be polled to determine the end of the erase cycle before the CPU can access any flash address again. If a flash access occurs while BUSY=1, it is an access violation, ACCVIFG will be set, and the erase results will be unpredictable.

The flow to initiate an erase from RAM is shown in Figure 5–6.

Figure 5–6. Erase Cycle from Within RAM

```

; Segment Erase from RAM. 514 kHz < SMCLK < 952 kHz
; Assumes ACCVIE = NMIE = OFIE = 0.
MOV    #WDTPW+WDTHOLD,&WDTCTL    ; Disable WDT
L1 BIT  #BUSY,&FCTL3              ; Test BUSY
JNZ    L1                        ; Loop while busy
MOV    #FWKEY+FSSEL1+FN0,&FCTL2    ; SMCLK/2
MOV    #FWKEY,&FCTL3              ; Clear LOCK
MOV    #FWKEY+ERASE,&FCTL1        ; Enable erase
CLR    &0FC10h                   ; Dummy write, erase S1
L2 BIT  #BUSY,&FCTL3              ; Test BUSY
JNZ    L2                        ; Loop while busy
MOV    #FWKEY+LOCK,&FCTL3         ; Done, set LOCK
...                                         ; Re-enable WDT?
  
```

5.3.3 Writing Flash Memory

The write modes, selected by the WRT and BLKWRT bits, are listed in Table 5–1.

Table 5–2. Write Modes

BLKWRT	WRT	Write Mode
0	1	Byte/word write
1	1	Block write

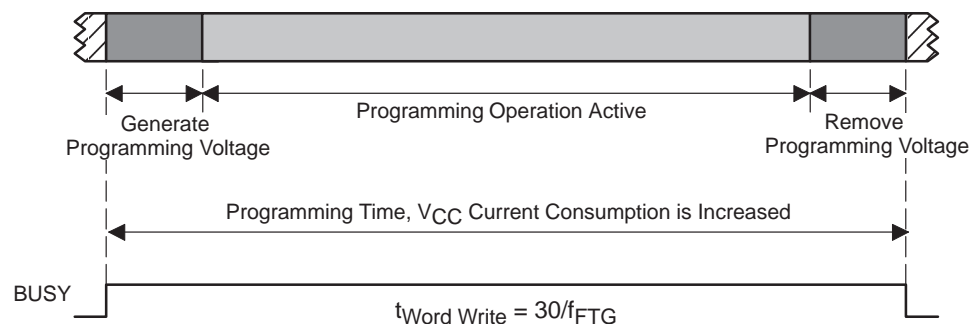

Both write modes use a sequence of individual write instructions, but using the block write mode is approximately twice as fast as byte/word mode, because the voltage generator remains on for the complete block write. Any instruction that modifies a destination can be used to modify a flash location in either byte/word mode or block-write mode. A flash word (low + high byte) must not be written more than twice between erasures. Otherwise, damage can occur.

The BUSY bit is set while a write operation is active and cleared when the operation completes. If the write operation is initiated from RAM, the CPU must not access flash while BUSY=1. Otherwise, an access violation occurs, ACCVIFG is set, and the flash write is unpredictable.

Byte/Word Write

A byte/word write operation can be initiated from within flash memory or from RAM. When initiating from within flash memory, all timing is controlled by the flash controller, and the CPU is held while the write completes. After the write completes, the CPU resumes code execution with the instruction following the write. The byte/word write timing is shown in Figure 5–7.

Figure 5–7. Byte/Word Write Timing

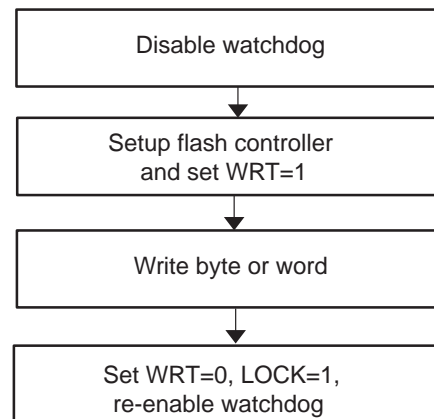

When a byte/word write is executed from RAM, the CPU continues to execute code from RAM. The BUSY bit must be zero before the CPU accesses flash again, otherwise an access violation occurs, ACCVIFG is set, and the write result is unpredictable.

In byte/word mode, the internally-generated programming voltage is applied to the complete 64-byte block, each time a byte or word is written, for 27 of the 30 f_{FTG} cycles. With each byte or word write, the amount of time the block is subjected to the programming voltage accumulates. The cumulative programming time, t_{CPT} , must not be exceeded for any block. If the cumulative programming time is met, the block must be erased before performing any further writes to any address within the block. See the device-specific datasheet for specifications.

Initiating a Byte/Word Write from Within Flash Memory

The flow to initiate a byte/word write from flash is shown in Figure 5–8.

Figure 5–8. Initiating a Byte/Word Write from Flash

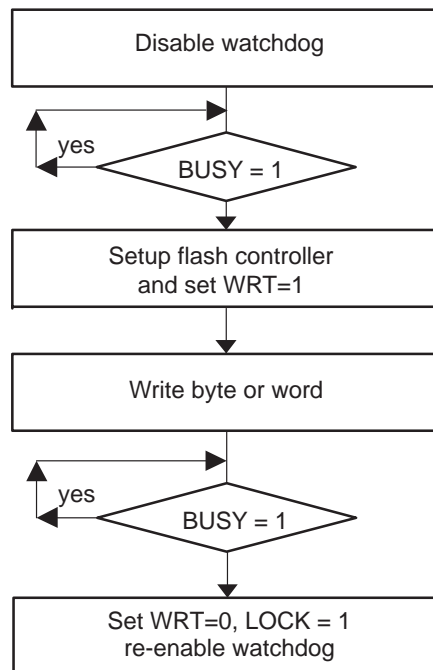

```

; Byte/word write from flash. 514 kHz < SMCLK < 952 kHz
; Assumes 0FF1Eh is already erased
; Assumes ACCVIE = NMIIE = OFIE = 0.
MOV    #WDT PW+WDTHOLD,&WDTCTL    ; Disable WDT
MOV    #FWKEY+FSSEL1+FN0,&FCTL2    ; SMCLK/2
MOV    #FWKEY,&FCTL3                ; Clear LOCK
MOV    #FWKEY+WRT,&FCTL1            ; Enable write
MOV    #0123h,&0FF1Eh               ; 0123h -> 0FF1Eh
MOV    #FWKEY,&FCTL1                ; Done. Clear WRT
MOV    #FWKEY+LOCK,&FCTL3           ; Set LOCK
...
; Re-enable WDT?
  
```

Initiating a Byte/Word Write from RAM

The flow to initiate a byte/word write from RAM is shown in Figure 5–9.

Figure 5–9. Initiating a Byte/Word Write from RAM

```

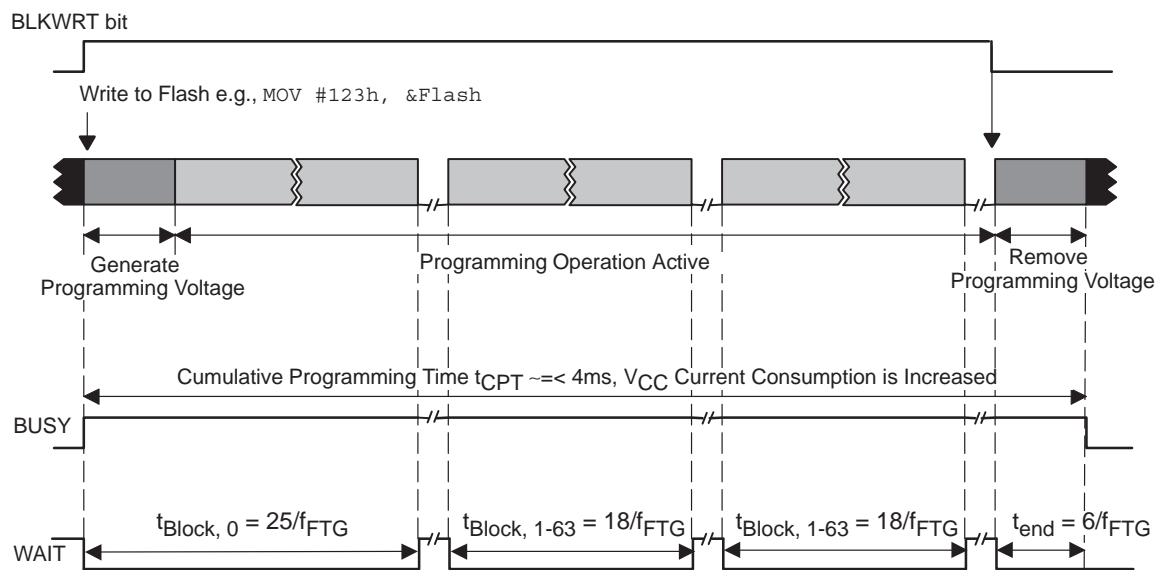

; Byte/word write from RAM. 514 kHz < SMCLK < 952 kHz
; Assumes 0FF1Eh is already erased
; Assumes ACCVIE = NMIIIE = OFIE = 0.
MOV    #WDTPW+WDTHOLD,&WDTCTL    ; Disable WDT
L1 BIT  #BUSY,&FCTL3              ; Test BUSY
JNZ    L1                        ; Loop while busy
MOV    #FWKEY+FSSEL1+FN0,&FCTL2   ; SMCLK/2
MOV    #FWKEY,&FCTL3              ; Clear LOCK
MOV    #FWKEY+WRT,&FCTL1          ; Enable write
MOV    #0123h,&0FF1Eh            ; 0123h -> 0FF1Eh
L2 BIT  #BUSY,&FCTL3              ; Test BUSY
JNZ    L2                        ; Loop while busy
MOV    #FWKEY,&FCTL1              ; Clear WRT
MOV    #FWKEY+LOCK,&FCTL3         ; Set LOCK
...
; Re-enable WDT?
  
```

Block Write

The block write can be used to accelerate the flash write process when many sequential bytes or words need to be programmed. The flash programming voltage remains on for the duration of writing the 64-byte block. The cumulative programming time t_{CPT} must not be exceeded for any block during a block write.

A block write cannot be initiated from within flash memory. The block write must be initiated from RAM only. The BUSY bit remains set throughout the duration of the block write. The WAIT bit must be checked between writing each byte or word in the block. When WAIT is set the next byte or word of the block can be written. When writing successive blocks, the BLKWRT bit must be cleared after the current block is complete. BLKWRT can be set initiating the next block write after the required flash recovery time given by t_{end} . BUSY is cleared following each block write completion indicating the next block can be written. Figure 5–10 shows the block write timing.

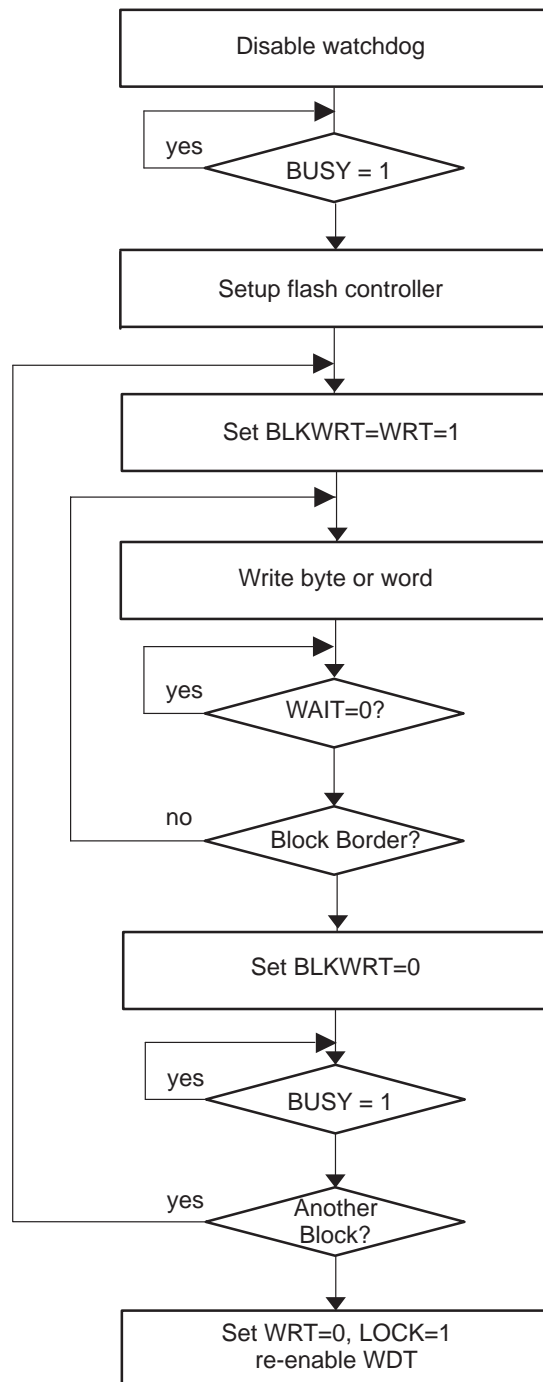

Figure 5–10. Block-Write Cycle Timing

Block Write Flow and Example

A block write flow is shown in Figure 5–8 and the following example.

Figure 5–11. Block Write Flow

```

; Write one block starting at 0F000h.
; Must be executed from RAM, Assumes Flash is already erased.
; 514 kHz < SMCLK < 952 kHz
; Assumes ACCVIE = NMIIE = OFIE = 0.
MOV    #32,R5                ; Use as write counter
MOV    #0F000h,R6            ; Write pointer
MOV    #WDT PW+WDTHOLD,&WDTCTL ; Disable WDT

...    ; Re-enable WDT if needed

```

5.3.4 Flash Memory Access During Write or Erase

When any write or any erase operation is initiated from RAM and while $BUSY=1$, the CPU may not read or write to or from any flash location. Otherwise, an access violation occurs, $ACCVIFG$ is set, and the result is unpredictable. Also if a write to flash is attempted with $WRT=0$, the $ACCVIFG$ interrupt flag is set, and the flash memory is unaffected.

When a byte/word write or any erase operation is initiated from within flash memory, the flash controller returns op-code 03FFFh to the CPU at the next instruction fetch. Op-code 03FFFh is the `JMP PC` instruction. This causes the CPU to loop until the flash operation is finished. When the operation is finished and $BUSY=0$, the flash controller allows the CPU to fetch the proper op-code and program execution resumes.

The flash access conditions while $BUSY=1$ are listed in Table 5–3.

Table 5–3. Flash Access While $BUSY = 1$

Flash Operation	Flash Access	WAIT	Result
Any erase, or Byte/word write	Read	0	$ACCVIFG = 0$. 03FFFh is the value read
	Write	0	$ACCVIFG = 1$. Write is ignored
	Instruction fetch	0	$ACCVIFG = 0$. CPU fetches 03FFFh. This is the <code>JMP PC</code> instruction.
Block write	Any	0	$ACCVIFG = 1$, $LOCK = 1$
	Read	1	$ACCVIFG = 0$, 03FFFh is the value read
	Write	1	$ACCVIFG = 0$, Flash is written
	Instruction fetch	1	$ACCVIFG = 1$, $LOCK = 1$

Interrupts are automatically disabled during any flash operation when $EEL = 0$ and $EEIEX = 0$ and on MSP430x20xx devices where EEL and $EEIEX$ are not present. After the flash operation has completed, interrupts are automatically re-enabled. Any interrupt that occurred during the operation will have its associated flag set, and will generate an interrupt request when re-enabled.

When $EEIEX = 1$ and $GIE = 1$, an interrupt will immediately abort any flash operation and the $FAIL$ flag will be set. When $EEL = 1$, $GIE = 1$, and $EEIEX = 0$, a segment erase will be interrupted by a pending interrupt every $32 f_{FTG}$ cycles. After servicing the interrupt, the segment erase is continued for at least $32 f_{FTG}$ cycles or until it is complete. During the servicing of the interrupt, the $BUSY$ bit remains set but the flash memory can be accessed by the CPU without causing an access violation occurs. Nested interrupts are not supported.

The watchdog timer (in watchdog mode) should be disabled before a flash erase cycle. A reset will abort the erase and the result will be unpredictable. After the erase cycle has completed, the watchdog may be re-enabled.

5.3.5 Stopping a Write or Erase Cycle

Any write or erase operation can be stopped before its normal completion by setting the emergency exit bit EMEX. Setting the EMEX bit stops the active operation immediately and stops the flash controller. All flash operations cease, the flash returns to read mode, and all bits in the FCTL1 register are reset. The result of the intended operation is unpredictable.

5.3.6 Configuring and Accessing the Flash Memory Controller

The FCTLx registers are 16-bit, password-protected, read/write registers. Any read or write access must use word instructions and write accesses must include the write password 0A5h in the upper byte. Any write to any FCTLx register with any value other than 0A5h in the upper byte is a security key violation, sets the KEYV flag and triggers a PUC system reset. Any read of any FCTLx registers reads 096h in the upper byte.

Any write to FCTL1 during an erase or byte/word write operation is an access violation and sets ACCVIFG. Writing to FCTL1 is allowed in block write mode when WAIT=1, but writing to FCTL1 in block write mode when WAIT=0 is an access violation and sets ACCVIFG.

Any write to FCTL2 when the BUSY=1 is an access violation.

Any FCTLx register may be read when BUSY=1. A read will not cause an access violation.

5.3.7 Flash Memory Controller Interrupts

The flash controller has two interrupt sources, KEYV, and ACCVIFG. ACCVIFG is set when an access violation occurs. When the ACCVIE bit is re-enabled after a flash write or erase, a set ACCVIFG flag will generate an interrupt request. ACCVIFG sources the NMI interrupt vector, so it is not necessary for GIE to be set for ACCVIFG to request an interrupt. ACCVIFG may also be checked by software to determine if an access violation occurred. ACCVIFG must be reset by software.

The key violation flag KEYV is set when any of the flash control registers are written with an incorrect password. When this occurs, a PUC is generated immediately resetting the device.

5.3.8 Programming Flash Memory Devices

There are three options for programming an MSP430 flash device. All options support in-system programming:

- ☐ Program via JTAG
- ☐ Program via the Bootstrap Loader
- ☐ Program via a custom solution

Programming Flash Memory via JTAG

MSP430 devices can be programmed via the JTAG port. The JTAG interface requires four signals (5 signals on 20- and 28-pin devices), ground and optionally V_{CC} and \overline{RST}/NMI .

The JTAG port is protected with a fuse. Blowing the fuse completely disables the JTAG port and is not reversible. Further access to the device via JTAG is not possible. For more details see the Application report *Programming a Flash-Based MSP430 Using the JTAG Interface* at www.msp430.com.

Programming Flash Memory via the Bootstrap loader (BSL)

Every MSP430 flash device contains a bootstrap loader. The BSL enables users to read or program the flash memory or RAM using a UART serial interface. Access to the MSP430 flash memory via the BSL is protected by a 256-bit, user-defined password. For more details see the Application report *Features of the MSP430 Bootstrap Loader* at www.ti.com/msp430.

Programming Flash Memory via a Custom Solution

The ability of the MSP430 CPU to write to its own flash memory allows for in-system and external custom programming solutions as shown in Figure 5–12. The user can choose to provide data to the MSP430 through any means available (UART, SPI, etc.). User-developed software can receive the data and program the flash memory. Since this type of solution is developed by the user, it can be completely customized to fit the application needs for programming, erasing, or updating the flash memory.

Figure 5–12. User-Developed Programming Solution

5.4 Flash Memory Registers

The flash memory registers are listed in Table 5–4.

Table 5–4. Flash Memory Registers

Register	Short Form	Register Type	Address	Initial State
Flash memory control register 1	FCTL1	Read/write	0128h	09600h with PUC
Flash memory control register 2	FCTL2	Read/write	012Ah	09642h with PUC
Flash memory control register 3	FCTL3	Read/write	012Ch	09658h with PUC
Interrupt Enable 1	IE1	Read/write	000h	Reset with PUC

FCTL1, Flash Memory Control Register

15	14	13	12	11	10	9	8
FRKEY, Read as 096h FWKEY, Must be written as 0A5h							
7	6	5	4	3	2	1	0
BLKWRT	WRT	Reserved	EEIEX†	EEI†	MERAS	ERASE	Reserved
rw-0	rw-0	r0	rw-0	rw-0	rw-0	rw-0	r0

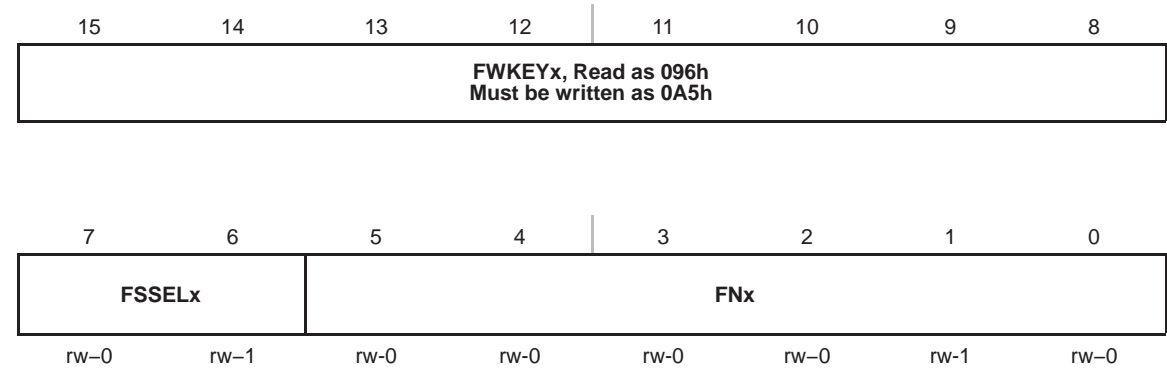

† Not present on MSP430x20xx Devices

FRKEY/ FWKEY	Bits 15-8	FCTLx password. Always read as 096h. Must be written as 0A5h or a PUC will be generated.
BLKWRT	Bit 7	Block write mode. WRT must also be set for block write mode. BLKWRT is automatically reset when EMEX is set. 0 Block-write mode is off 1 Block-write mode is on
WRT	Bit 6	Write. This bit is used to select any write mode. WRT is automatically reset when EMEX is set. 0 Write mode is off 1 Write mode is on
Reserved	Bit 5	Reserved. Always read as 0.
EEIEX	Bit 4	Enable Emergency Interrupt Exit. Setting this bit enables an interrupt to cause an emergency exit from a flash operation when GIE = 1. EEIEX is automatically reset when EMEX is set. 0 Exit interrupt disabled. 1 Exit on interrupt enabled.
EEI	Bits 3	Enable Erase Interrupts. Setting this bit allows a segment erase to be interrupted by an interrupt request. After the interrupt is serviced the erase cycle is resumed. EEI is automatically reset when EMEX is set. 0 Interrupts during segment erase disabled. 1 Interrupts during segment erase enabled.
MERAS ERASE	Bit 2 Bit 1	Mass erase and erase. These bits are used together to select the erase mode. MERAS and ERASE are automatically reset when EMEX is set.

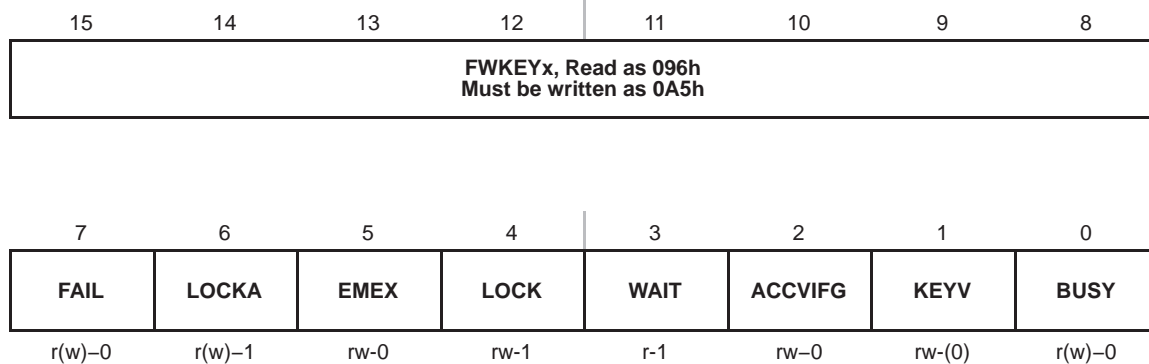

MERAS	ERASE	Erase Cycle
0	0	No erase
0	1	Erase individual segment only
1	0	Erase all main memory segments
1	1	Erase all main and information memory segments if LOCKA = 0. Main segments only if LOCKA = 1.

Reserved	Bit 0	Reserved. Always read as 0.
-----------------	-------	-----------------------------

FCTL2, Flash Memory Control Register

FWKEYx	Bits 15-8	FCTLx password. Always read as 096h. Must be written as 0A5h or a PUC will be generated.
FSSELx	Bits 7-6	Flash controller clock source select 00 ACLK 01 MCLK 10 SMCLK 11 SMCLK
FNx	Bits 5-0	Flash controller clock divider. These six bits select the divider for the flash controller clock. The divisor value is FNx + 1. For example, when FNx=00h, the divisor is 1. When FNx=03Fh the divisor is 64.

FCTL3, Flash Memory Control Register FCTL3

FWKEYx	Bits 15-8	FCTLx password. Always read as 096h. Must be written as 0A5h or a PUC will be generated.
FAIL	Bit 7	<p>Operation failure. This bit is set if the f_{FTG} clock source fails, or a flash operation is aborted from an interrupt when $EEIEX = 1$. FAIL must be reset with software.</p> <p>0 No failure</p> <p>1 Failure</p>
LOCKA	Bit 6	<p>SegmentA and Info lock. Write a 1 to this bit to change its state. Writing 0 has no effect.</p> <p>0 Segment A unlocked and all information memory is erased during a mass erase.</p> <p>1 Segment A locked and all information memory is protected from erasure during a mass erase.</p>
EMEX	Bit 5	<p>Emergency exit</p> <p>0 No emergency exit</p> <p>1 Emergency exit</p>
LOCK	Bit 4	<p>Lock. This bit unlocks the flash memory for writing or erasing. The LOCK bit can be set anytime during a byte/word write or erase operation and the operation will complete normally. In the block write mode if the LOCK bit is set while $BLKWRT=WAIT=1$, then $BLKWRT$ and $WAIT$ are reset and the mode ends normally.</p> <p>0 Unlocked</p> <p>1 Locked</p>
WAIT	Bit 3	<p>Wait. Indicates the flash memory is being written to.</p> <p>0 The flash memory is not ready for the next byte/word write</p> <p>1 The flash memory is ready for the next byte/word write</p>
ACCVIFG	Bit 2	<p>Access violation interrupt flag. ACCVIFG must be reset with software.</p> <p>0 No interrupt pending</p> <p>1 Interrupt pending</p>

KEYV	Bit 1	Flash security key violation. This bit indicates an incorrect FCTLx password was written to any flash control register and generates a PUC when set. KEYV must be reset with software. 0 FCTLx password was written correctly 1 FCTLx password was written incorrectly
BUSY	Bit 0	Busy. This bit indicates the status of the flash timing generator. 0 Not Busy 1 Busy

IE1, Interrupt Enable Register 1

7	6	5	4	3	2	1	0
		ACCVIE					
rw-0							

Bits 7-6, 4-0 These bits may be used by other modules. See device-specific datasheet.

ACCVIE	Bit 5	Flash memory access violation interrupt enable. This bit enables the ACCVIFG interrupt. Because other bits in IE1 may be used for other modules, it is recommended to set or clear this bit using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions. 0 Interrupt not enabled 1 Interrupt enabled
---------------	-------	---

Digital I/O

This chapter describes the operation of the digital I/O ports.

Topic	Page
6.1 Digital I/O Introduction	6-2
6.2 Digital I/O Operation	6-3
6.3 Digital I/O Registers	6-7

6.1 Digital I/O Introduction

MSP430 devices have up to six digital I/O ports implemented, P1–P6. Each port has eight I/O pins. Every I/O pin is individually configurable for input or output direction, and each I/O line can be individually read or written to.

Ports P1 and P2 have interrupt capability. Each interrupt for the P1 and P2 I/O lines can be individually enabled and configured to provide an interrupt on a rising edge or falling edge of an input signal. All P1 I/O lines source a single interrupt vector, and all P2 I/O lines source a different, single interrupt vector.

The digital I/O features include:

- ☐ Independently programmable individual I/Os
- ☐ Any combination of input or output
- ☐ Individually configurable P1 and P2 interrupts
- ☐ Independent input and output data registers
- ☐ Individually configurable pull-up or pull-down resistors

6.2 Digital I/O Operation

The digital I/O is configured with user software. The setup and operation of the digital I/O is discussed in the following sections.

6.2.1 Input Register PxIN

Each bit in each PxIN register reflects the value of the input signal at the corresponding I/O pin when the pin is configured as I/O function.

Bit = 0: The input is low

Bit = 1: The input is high

Note: Writing to Read-Only Registers PxIN

Writing to these read-only registers results in increased current consumption while the write attempt is active.

6.2.2 Output Registers PxOUT

Each bit in each PxOUT register is the value to be output on the corresponding I/O pin when the pin is configured as I/O function, output direction, and the pull-up/down resistor is disabled.

Bit = 0: The output is low

Bit = 1: The output is high

If the pin's pull-up/down resistor is enabled, the corresponding bit in the PxOUT register selects pull-up or pull-down.

Bit = 0: The pin is pulled down

Bit = 1: The pin is pulled up

6.2.3 Direction Registers PxDIR

Each bit in each PxDIR register selects the direction of the corresponding I/O pin, regardless of the selected function for the pin. PxDIR bits for I/O pins that are selected for other functions must be set as required by the other function.

Bit = 0: The port pin is switched to input direction

Bit = 1: The port pin is switched to output direction

6.2.4 Pull-Up/Down Resistor Enable Registers PxREN

Each bit in each PxREN register enables or disables the pull-up/down resistor of the corresponding I/O pin. The corresponding bit in the PxOUT register selects if the pin is pulled up or pulled down.

Bit = 0: Pull-up/down resistor disabled

Bit = 1: Pull-up/down resistor enabled

6.2.5 Function Select Registers PxSEL

Port pins are often multiplexed with other peripheral module functions. See the device-specific data sheet to determine pin functions. Each PxSEL bit is used to select the pin function – I/O port or peripheral module function.

Bit = 0: I/O Function is selected for the pin

Bit = 1: Peripheral module function is selected for the pin

Setting PxSELx = 1 does not automatically set the pin direction. Other peripheral module functions may require the PxDIRx bits to be configured according to the direction needed for the module function. See the pin schematics in the device-specific datasheet.

```
;Output ACLK on P2.0 on MSP430F21x1
    BIS.B #01h,&P2SEL ; Select ACLK function for pin
    BIS.B #01h,&P2DIR ; Set direction to output *Required*
```

Note: P1 and P2 Interrupts Are Disabled When PxSEL = 1

When any P1SELx or P2SELx bit is set, the corresponding pin's interrupt function is disabled. Therefore, signals on these pins will not generate P1 or P2 interrupts, regardless of the state of the corresponding P1IE or P2IE bit.

When a port pin is selected as an input to a peripheral, the input signal to the peripheral is a latched representation of the signal at the device pin. While PxSELx=1, the internal input signal follows the signal at the pin. However, if the PxSELx=0, the input to the peripheral maintains the value of the input signal at the device pin before the PxSELx bit was reset.

6.2.6 P1 and P2 Interrupts

Each pin in ports P1 and P2 have interrupt capability, configured with the PxIFG, PxIE, and PxIES registers. All P1 pins source a single interrupt vector, and all P2 pins source a different single interrupt vector. The PxIFG register can be tested to determine the source of a P1 or P2 interrupt.

Interrupt Flag Registers P1IFG, P2IFG

Each PxIFGx bit is the interrupt flag for its corresponding I/O pin and is set when the selected input signal edge occurs at the pin. All PxIFGx interrupt flags request an interrupt when their corresponding PxIE bit and the GIE bit are set. Each PxIFG flag must be reset with software. Software can also set each PxIFG flag, providing a way to generate a software initiated interrupt.

Bit = 0: No interrupt is pending

Bit = 1: An interrupt is pending

Only transitions, not static levels, cause interrupts. If any PxIFGx flag becomes set during a Px interrupt service routine, or is set after the RETI instruction of a Px interrupt service routine is executed, the set PxIFGx flag generates another interrupt. This ensures that each transition is acknowledged.

Note: PxIFG Flags When Changing PxOUT or PxDIR

Writing to P1OUT, P1DIR, P2OUT, or P2DIR can result in setting the corresponding P1IFG or P2IFG flags.

Interrupt Edge Select Registers P1IES, P2IES

Each PxIES bit selects the interrupt edge for the corresponding I/O pin.

Bit = 0: The PxIFGx flag is set with a low-to-high transition

Bit = 1: The PxIFGx flag is set with a high-to-low transition

Note: Writing to PxIESx

Writing to P1IES, or P2IES can result in setting the corresponding interrupt flags.

PxIESx	PxINx	PxIFGx
0 → 1	0	May be set
0 → 1	1	Unchanged
1 → 0	0	Unchanged
1 → 0	1	May be set

Interrupt Enable P1IE, P2IE

Each PxIE bit enables the associated PxIFG interrupt flag.

Bit = 0: The interrupt is disabled

Bit = 1: The interrupt is enabled

6.2.7 Configuring Unused Port Pins

Unused I/O pins should be configured as I/O function, output direction, and left unconnected on the PC board, to prevent a floating input and reduce power consumption. The value of the PxOUT bit is don't care, since the pin is unconnected. Alternatively, the integrated pull-up/down resistor can be enabled by setting the PxREN bit of the unused pin to prevent the floating input. See chapter *System Resets, Interrupts, and Operating Modes* for termination unused pins.

6.3 Digital I/O Registers

The digital I/O registers are listed in Table 6–1.

Table 6–1. Digital I/O Registers

Port	Register	Short Form	Address	Register Type	Initial State
P1	Input	P1IN	020h	Read only	–
	Output	P1OUT	021h	Read/write	Unchanged
	Direction	P1DIR	022h	Read/write	Reset with PUC
	Interrupt Flag	P1IFG	023h	Read/write	Reset with PUC
	Interrupt Edge Select	P1IES	024h	Read/write	Unchanged
	Interrupt Enable	P1IE	025h	Read/write	Reset with PUC
	Port Select	P1SEL	026h	Read/write	Reset with PUC
	Resistor Enable	P1REN	027h	Read/write	Reset with PUC
P2	Input	P2IN	028h	Read only	–
	Output	P2OUT	029h	Read/write	Unchanged
	Direction	P2DIR	02Ah	Read/write	Reset with PUC
	Interrupt Flag	P2IFG	02Bh	Read/write	Reset with PUC
	Interrupt Edge Select	P2IES	02Ch	Read/write	Unchanged
	Interrupt Enable	P2IE	02Dh	Read/write	Reset with PUC
	Port Select	P2SEL	02Eh	Read/write	0C0h with PUC
	Resistor Enable	P2REN	02Fh	Read/write	Reset with PUC

	Port Select	P4SEL	01Fh	Read/write	Reset with PUC
	Resistor Enable	P4REN	011h	Read/write	Reset with PUC
P5	Input	P5IN	030h	Read only	–
	Output	P5OUT	031h	Read/write	Unchanged
	Direction	P5DIR	032h	Read/write	Reset with PUC
	Port Select	P5SEL	033h	Read/write	Reset with PUC
	Resistor Enable	P5REN	012h	Read/write	Reset with PUC
P6	Input	P6IN	034h	Read only	–
	Output	P6OUT	035h	Read/write	Unchanged
	Direction	P6DIR	036h	Read/write	Reset with PUC
	Port Select	P6SEL	037h	Read/write	Reset with PUC
	Resistor Enable	P6REN	013h	Read/write	Reset with PUC

Watchdog Timer+

The watchdog timer+ (WDT+) is a 16-bit timer that can be used as a watchdog or as an interval timer. This chapter describes the WDT+. The WDT+ is implemented in all MSP430x2xx devices.

Topic	Page
7.1 Watchdog Timer+ Introduction	7-2
7.2 Watchdog Timer+ Operation	7-4
7.3 Watchdog Timer+ Registers	7-7

7.1 Watchdog Timer+ Introduction

The primary function of the watchdog timer+ (WDT+) module is to perform a controlled system restart after a software problem occurs. If the selected time interval expires, a system reset is generated. If the watchdog function is not needed in an application, the module can be configured as an interval timer and can generate interrupts at selected time intervals.

Features of the watchdog timer+ module include:

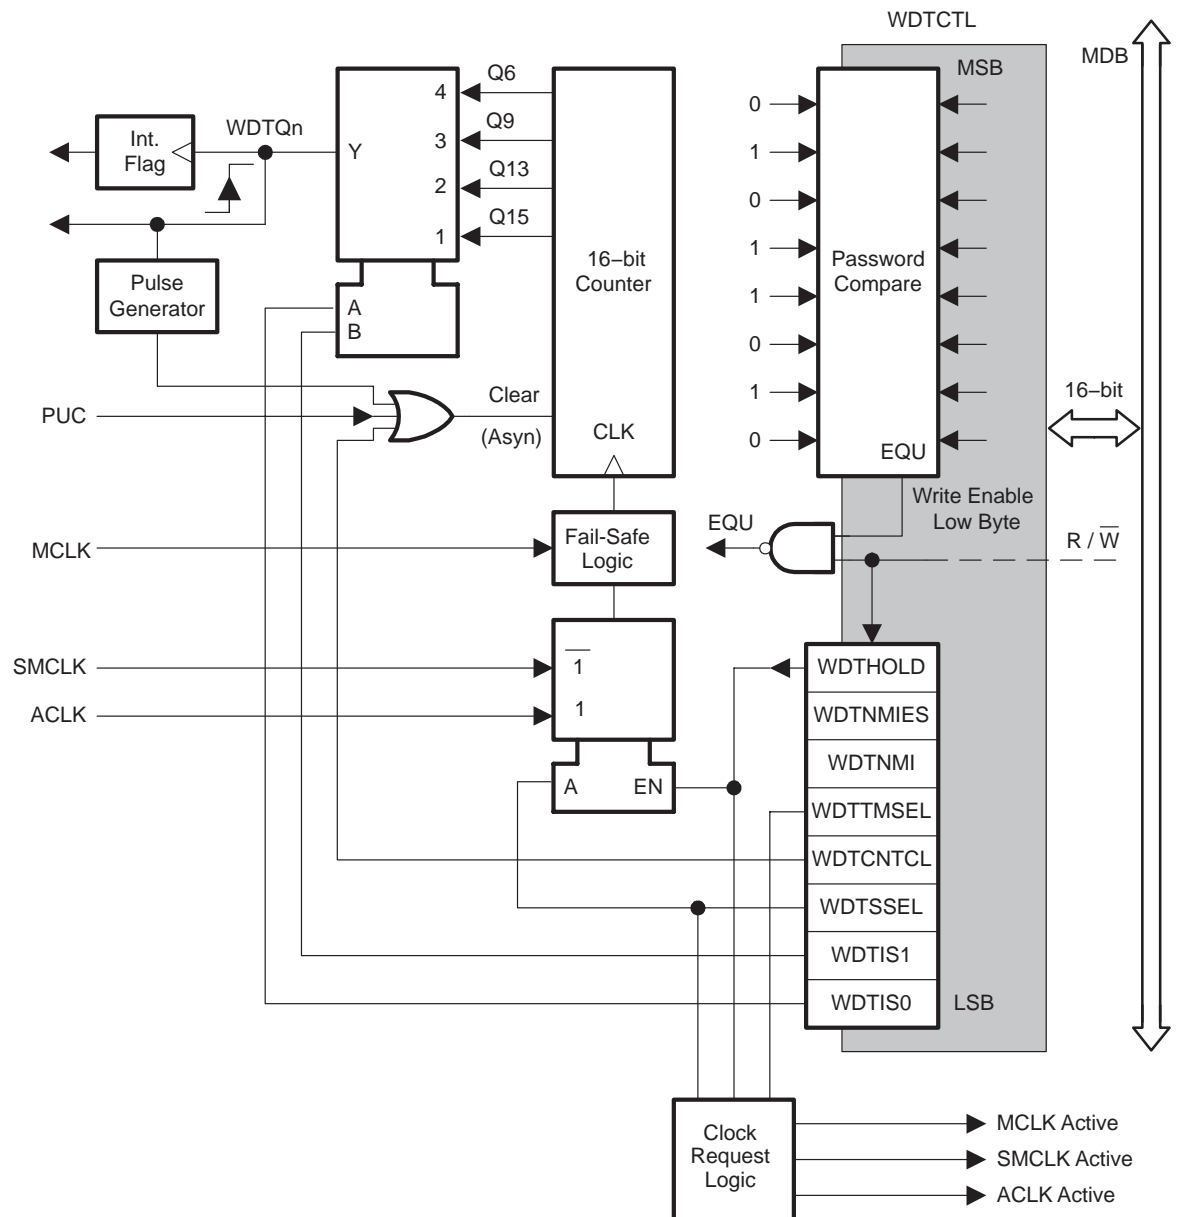

- ☐ Four software-selectable time intervals
- ☐ Watchdog mode
- ☐ Interval mode
- ☐ Access to WDT+ control register is password protected
- ☐ Control of $\overline{\text{RST}}$ /NMI pin function
- ☐ Selectable clock source
- ☐ Can be stopped to conserve power
- ☐ Clock fail-safe feature

The WDT+ block diagram is shown in Figure 7–1.

Note: Watchdog timer+ Powers Up Active

After a PUC, the WDT+ module is automatically configured in the watchdog mode with an initial 32768 clock cycle reset interval using the DCOCLK. The user must setup or halt the WDT+ prior to the expiration of the initial reset interval.

Figure 7-1. Watchdog Timer+ Block Diagram

7.2 Watchdog Timer+ Operation

The WDT+ module can be configured as either a watchdog or interval timer with the WDTCTL register. The WDTCTL register also contains control bits to configure the $\overline{\text{RST}}/\text{NMI}$ pin. WDTCTL is a 16-bit, password-protected, read/write register. Any read or write access must use word instructions and write accesses must include the write password 05Ah in the upper byte. Any write to WDTCTL with any value other than 05Ah in the upper byte is a security key violation and triggers a PUC system reset regardless of timer mode. Any read of WDTCTL reads 069h in the upper byte. The WDT+ counter clock should be slower or equal than the system (MCLK) frequency.

7.2.1 Watchdog timer+ Counter

The watchdog timer+ counter (WDCNT) is a 16-bit up-counter that is not directly accessible by software. The WDCNT is controlled and time intervals selected through the watchdog timer+ control register WDTCTL.

The WDCNT can be sourced from ACLK or SMCLK. The clock source is selected with the WDTSSEL bit.

7.2.2 Watchdog Mode

After a PUC condition, the WDT+ module is configured in the watchdog mode with an initial ~32-ms reset interval using the DCOCLK. The user must setup, halt, or clear the WDT+ prior to the expiration of the initial reset interval or another PUC will be generated. When the WDT+ is configured to operate in watchdog mode, either writing to WDTCTL with an incorrect password, or expiration of the selected time interval triggers a PUC. A PUC resets the WDT+ to its default condition and configures the $\overline{\text{RST}}/\text{NMI}$ pin to reset mode.

7.2.3 Interval Timer Mode

Setting the WDTTMSSEL bit to 1 selects the interval timer mode. This mode can be used to provide periodic interrupts. In interval timer mode, the WDTIFG flag is set at the expiration of the selected time interval. A PUC is not generated in interval timer mode at expiration of the selected timer interval and the WDTIFG enable bit WDTIE remains unchanged.

When the WDTIE bit and the GIE bit are set, the WDTIFG flag requests an interrupt. The WDTIFG interrupt flag is automatically reset when its interrupt request is serviced, or may be reset by software. The interrupt vector address in interval timer mode is different from that in watchdog mode.

Note: Modifying the Watchdog timer+

The WDT+ interval should be changed together with WDTCNTCL = 1 in a single instruction to avoid an unexpected immediate PUC or interrupt.

The WDT+ should be halted before changing the clock source to avoid a possible incorrect interval.

7.2.4 Watchdog timer+ Interrupts

The WDT+ uses two bits in the SFRs for interrupt control.

- ☐ The WDT+ interrupt flag, WDTIFG, located in IFG1.0
- ☐ The WDT+ interrupt enable, WDTIE, located in IE1.0

When using the WDT+ in the watchdog mode, the WDTIFG flag sources a reset vector interrupt. The WDTIFG can be used by the reset interrupt service routine to determine if the watchdog caused the device to reset. If the flag is set, then the watchdog timer+ initiated the reset condition either by timing out or by a security key violation. If WDTIFG is cleared, the reset was caused by a different source.

When using the WDT+ in interval timer mode, the WDTIFG flag is set after the selected time interval and requests a WDT+ interval timer interrupt if the WDTIE and the GIE bits are set. The interval timer interrupt vector is different from the reset vector used in watchdog mode. In interval timer mode, the WDTIFG flag is reset automatically when the interrupt is serviced, or can be reset with software.

7.2.5 Watchdog timer+ Clock Fail-safe Operation

The WDT+ module provides a fail-safe clocking feature assuring the clock to the WDT+ cannot be disabled while in watchdog mode. This means the low-power modes may be affected by the choice for the WDT+ clock. For example, if ACLK is the WDT+ clock source, LPM4 will not be available, because the WDT+ will prevent ACLK from being disabled. Also, if ACLK or SMCLK fail while sourcing the WDT+, the WDT+ clock source is automatically switched to MCLK. In this case, if MCLK is sourced from a crystal, and the crystal has failed, the fail-safe feature will activate the DCO and use it as the source for MCLK.

When the WDT+ module is used in interval timer mode, there is no fail-safe feature for the clock source.

7.2.6 Operation in Low-Power Modes

The MSP430 devices have several low-power modes. Different clock signals are available in different low-power modes. The requirements of the user's application and the type of clocking used determine how the WDT+ should be configured. For example, the WDT+ should not be configured in watchdog mode with SMCLK as its clock source if the user wants to use low-power mode 3 because the WDT+ will keep SMCLK enabled for its clock source, increasing the current consumption of LPM3. When the watchdog timer+ is not required, the WDTHOLD bit can be used to hold the WDTCNT, reducing power consumption.

7.2.7 Software Examples

Any write operation to WDTCTL must be a word operation with 05Ah (WDTPW) in the upper byte:

```
; Periodically clear an active watchdog
    MOV #WDTPW+WDTCNTCL,&WDTCTL
;
; Change watchdog timer+ interval
    MOV #WDTPW+WDTCNTL+SSEL,&WDTCTL
;
; Stop the watchdog
    MOV #WDTPW+WDTHOLD,&WDTCTL
;
; Change WDT+ to interval timer mode, clock/8192 interval
    MOV #WDTPW+WDTCNTCL+WDTTMSSEL+WDTIS0,&WDTCTL
```

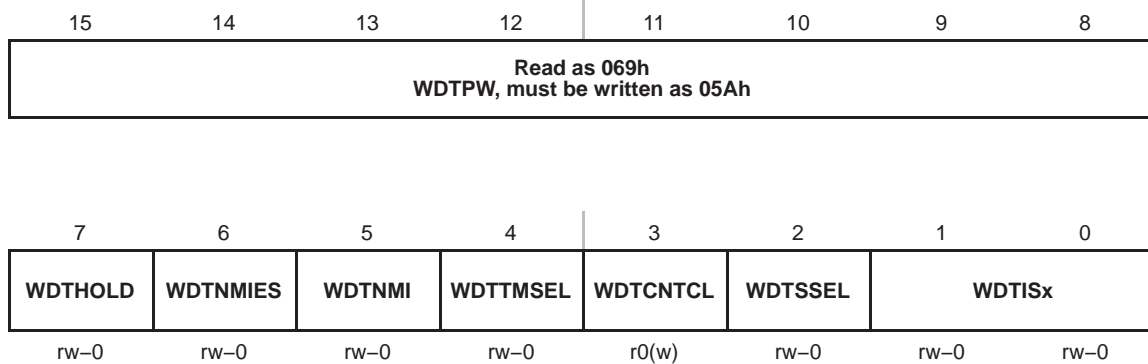

7.3 Watchdog Timer+ Registers

The WDT+ registers are listed in Table 7–1.

Table 7–1. Watchdog timer+ Registers

Register	Short Form	Register Type	Address	Initial State
Watchdog timer+ control register	WDTCTL	Read/write	0120h	06900h with PUC
SFR interrupt enable register 1	IE1	Read/write	0000h	Reset with PUC
SFR interrupt flag register 1	IFG1	Read/write	0002h	Reset with PUC†

† WDTIFG is reset with POR

WDTCTL, Watchdog timer+ Register

WDTPW	Bits 15-8	Watchdog timer+ password. Always read as 069h. Must be written as 05Ah, or a PUC will be generated.
WDTHOLD	Bit 7	Watchdog timer+ hold. This bit stops the watchdog timer+. Setting WDTHOLD = 1 when the WDT+ is not in use conserves power. 0 Watchdog timer+ is not stopped 1 Watchdog timer+ is stopped
WDTNMIES	Bit 6	Watchdog timer+ NMI edge select. This bit selects the interrupt edge for the NMI interrupt when WDTNMI = 1. Modifying this bit can trigger an NMI. Modify this bit when WDTNMI = 0 to avoid triggering an accidental NMI. 0 NMI on rising edge 1 NMI on falling edge
WDTNMI	Bit 5	Watchdog timer+ NMI select. This bit selects the function for the $\overline{\text{RST}}$ /NMI pin. 0 Reset function 1 NMI function
WDTTMSSEL	Bit 4	Watchdog timer+ mode select 0 Watchdog mode 1 Interval timer mode
WDTCNTCL	Bit 3	Watchdog timer+ counter clear. Setting WDTCNTCL = 1 clears the count value to 0000h. WDTCNTCL is automatically reset. 0 No action 1 WDTCNT = 0000h
WDTSSSEL	Bit 2	Watchdog timer+ clock source select 0 SMCLK 1 ACLK
WDTISx	Bits 1-0	Watchdog timer+ interval select. These bits select the watchdog timer+ interval to set the WDTIFG flag and/or generate a PUC. 00 Watchdog clock source /32768 01 Watchdog clock source /8192 10 Watchdog clock source /512 11 Watchdog clock source /64

IE1, Interrupt Enable Register 1

7	6	5	4	3	2	1	0
			NMIIE				WDTIE
rw-0							

	Bits 7-5	These bits may be used by other modules. See device-specific datasheet.
NMIIE	Bit 4	<p>NMI interrupt enable. This bit enables the NMI interrupt. Because other bits in IE1 may be used for other modules, it is recommended to set or clear this bit using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions.</p> <p>0 Interrupt not enabled 1 Interrupt enabled</p>
	Bits 3-1	These bits may be used by other modules. See device-specific datasheet.
WDTIE	Bit 0	<p>Watchdog timer+ interrupt enable. This bit enables the WDTIFG interrupt for interval timer mode. It is not necessary to set this bit for watchdog mode. Because other bits in IE1 may be used for other modules, it is recommended to set or clear this bit using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions.</p> <p>0 Interrupt not enabled 1 Interrupt enabled</p>

IFG1, Interrupt Flag Register 1

	Bits 7-5	These bits may be used by other modules. See device-specific datasheet.
NMIIFG	Bit 4	NMI interrupt flag. NMIIFG must be reset by software. Because other bits in IFG1 may be used for other modules, it is recommended to clear NMIIFG by using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions. 0 No interrupt pending 1 Interrupt pending
	Bits 3-1	These bits may be used by other modules. See device-specific datasheet.
WDTIFG	Bit 0	Watchdog timer+ interrupt flag. In watchdog mode, WDTIFG remains set until reset by software. In interval mode, WDTIFG is reset automatically by servicing the interrupt, or can be reset by software. Because other bits in IFG1 may be used for other modules, it is recommended to clear WDTIFG by using <code>BIS.B</code> or <code>BIC.B</code> instructions, rather than <code>MOV.B</code> or <code>CLR.B</code> instructions. 0 No interrupt pending 1 Interrupt pending

Hardware Multiplier

This chapter describes the hardware multiplier. The hardware multiplier is implemented in some MSP430x2xx devices.

Topic	Page
8.1 Hardware Multiplier Introduction	8-2
8.2 Hardware Multiplier Operation	8-3
8.3 Hardware Multiplier Registers	8-7

8.1 Hardware Multiplier Introduction

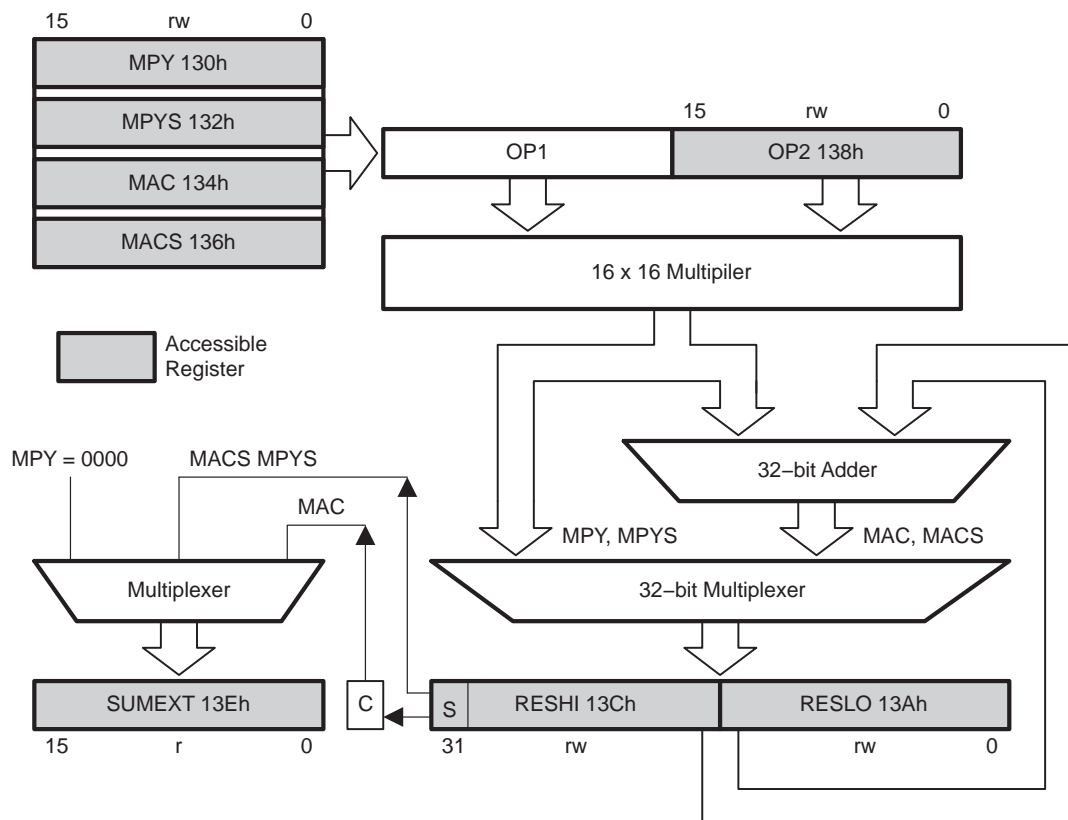

The hardware multiplier is a peripheral and is not part of the MSP430 CPU. This means, its activities do not interfere with the CPU activities. The multiplier registers are peripheral registers that are loaded and read with CPU instructions.

The hardware multiplier supports:

- ☐ Unsigned multiply
- ☐ Signed multiply
- ☐ Unsigned multiply accumulate
- ☐ Signed multiply accumulate
- ☐ 16×16 bits, 16×8 bits, 8×16 bits, 8×8 bits

The hardware multiplier block diagram is shown in Figure 8–1.

Figure 8–1. Hardware Multiplier Block Diagram

8.2 Hardware Multiplier Operation

The hardware multiplier supports unsigned multiply, signed multiply, unsigned multiply accumulate, and signed multiply accumulate operations. The type of operation is selected by the address the first operand is written to.

The hardware multiplier has two 16-bit operand registers, OP1 and OP2, and three result registers, RESLO, RESHI, and SUMEXT. RESLO stores the low word of the result, RESHI stores the high word of the result, and SUMEXT stores information about the result. The result is ready in three MCLK cycles and can be read with the next instruction after writing to OP2, except when using an indirect addressing mode to access the result. When using indirect addressing for the result, a `NOP` is required before the result is ready.

8.2.1 Operand Registers

The operand one register OP1 has four addresses, shown in Table 8–1, used to select the multiply mode. Writing the first operand to the desired address selects the type of multiply operation but does not start any operation. Writing the second operand to the operand two register OP2 initiates the multiply operation. Writing OP2 starts the selected operation with the values stored in OP1 and OP2. The result is written into the three result registers RESLO, RESHI, and SUMEXT.

Repeated multiply operations may be performed without reloading OP1 if the OP1 value is used for successive operations. It is not necessary to re-write the OP1 value to perform the operations.

Table 8–1. OP1 addresses

OP1 Address	Register Name	Operation
0130h	MPY	Unsigned multiply
0132h	MPYS	Signed multiply
0134h	MAC	Unsigned multiply accumulate
0136h	MACS	Signed multiply accumulate

8.2.2 Result Registers

The result low register RESLO holds the lower 16-bits of the calculation result. The result high register RESHI contents depend on the multiply operation and are listed in Table 8–2.

Table 8–2. RESHI Contents

Mode	RESHI Contents
MPY	Upper 16-bits of the result
MPYS	The MSB is the sign of the result. The remaining bits are the upper 15-bits of the result. Two's complement notation is used for the result.
MAC	Upper 16-bits of the result
MACS	Upper 16-bits of the result. Two's complement notation is used for the result.

The sum extension registers SUMEXT contents depend on the multiply operation and are listed in Table 8–3.

Table 8–3. SUMEXT Contents

Mode	SUMEXT
MPY	SUMEXT is always 0000h
MPYS	SUMEXT contains the extended sign of the result 00000h Result was positive or zero 0FFFFh Result was negative
MAC	SUMEXT contains the carry of the result 0000h No carry for result 0001h Result has a carry
MACS	SUMEXT contains the extended sign of the result 00000h Result was positive or zero 0FFFFh Result was negative

MACS Underflow and Overflow

The multiplier does not automatically detect underflow or overflow in the MACS mode. The accumulator range for positive numbers is 0 to 7FFF FFFFh and for negative numbers is 0FFFF FFFFh to 8000 0000h. An underflow occurs when the sum of two negative numbers yields a result that is in the range for a positive number. An overflow occurs when the sum of two positive numbers yields a result that is in the range for a negative number. In both of these cases, the SUMEXT register contains the sign of the result, 0FFFFh for overflow and 0000h for underflow. User software must detect and handle these conditions appropriately.

8.2.3 Software Examples

Examples for all multiplier modes follow. All 8x8 modes use the absolute address for the registers because the assembler will not allow .B access to word registers when using the labels from the standard definitions file.

There is no sign extension necessary in software. Accessing the multiplier with a byte instruction during a signed operation will automatically cause a sign extension of the byte within the multiplier module.

```
; 16x16 Unsigned Multiply
    MOV    #01234h,&MPY ; Load first operand
    MOV    #05678h,&OP2 ; Load second operand
; ...                               ; Process results

; 8x8 Unsigned Multiply. Absolute addressing.
    MOV.B  #012h,&0130h ; Load first operand
    MOV.B  #034h,&0138h ; Load 2nd operand
; ...                               ; Process results

; 16x16 Signed Multiply
    MOV    #01234h,&MPYS ; Load first operand
    MOV    #05678h,&OP2 ; Load 2nd operand
; ...                               ; Process results

; 8x8 Signed Multiply. Absolute addressing.
    MOV.B  #012h,&0132h ; Load first operand
    MOV.B  #034h,&0138h ; Load 2nd operand
; ...                               ; Process results

; 16x16 Unsigned Multiply Accumulate
    MOV    #01234h,&MAC ; Load first operand
    MOV    #05678h,&OP2 ; Load 2nd operand
; ...                               ; Process results

; 8x8 Unsigned Multiply Accumulate. Absolute addressing
    MOV.B  #012h,&0134h ; Load first operand
    MOV.B  #034h,&0138h ; Load 2nd operand
; ...                               ; Process results

; 16x16 Signed Multiply Accumulate
    MOV    #01234h,&MACS ; Load first operand
    MOV    #05678h,&OP2 ; Load 2nd operand
; ...                               ; Process results

; 8x8 Signed Multiply Accumulate. Absolute addressing
    MOV.B  #012h,&0136h ; Load first operand
    MOV.B  #034h,R5     ; Temp. location for 2nd operand
    MOV    R5,&OP2       ; Load 2nd operand
; ...                               ; Process results
```

8.2.4 Indirect Addressing of RESLO

When using indirect or indirect autoincrement addressing mode to access the result registers, At least one instruction is needed between loading the second operand and accessing one of the result registers:

```
; Access multiplier results with indirect addressing
MOV    #RESLO,R5    ; RESLO address in R5 for indirect
MOV    &OPER1,&MPY   ; Load 1st operand
MOV    &OPER2,&OP2   ; Load 2nd operand
NOP                      ; Need one cycle
MOV    @R5+,&xxx    ; Move RESLO
MOV    @R5,&xxx      ; Move RESHI
```

8.2.5 Using Interrupts

If an interrupt occurs after writing OP1, but before writing OP2, and the multiplier is used in servicing that interrupt, the original multiplier mode selection is lost and the results are unpredictable. To avoid this, disable interrupts before using the hardware multiplier or do not use the multiplier in interrupt service routines.

```
; Disable interrupts before using the hardware multiplier
DINT                      ; Disable interrupts
NOP                      ; Required for DINT
MOV    #xxh,&MPY ; Load 1st operand
MOV    #xxh,&OP2 ; Load 2nd operand
EINT                      ; Interrupts may be enable before
                        ; Process results
```

8.3 Hardware Multiplier Registers

The hardware multiplier registers are listed in Table 8–4.

Table 8–4. Hardware Multiplier Registers

Register	Short Form	Register Type	Address	Initial State
Operand one - multiply	MPY	Read/write	0130h	Unchanged
Operand one - signed multiply	MPYS	Read/write	0132h	Unchanged
Operand one - multiply accumulate	MAC	Read/write	0134h	Unchanged
Operand one - signed multiply accumulate	MACS	Read/write	0136h	Unchanged
Operand two	OP2	Read/write	0138h	Unchanged
Result low word	RESLO	Read/write	013Ah	Undefined
Result high word	RESHI	Read/write	013Ch	Undefined
Sum Extension register	SUMEXT	Read	013Eh	Undefined

Timer_A

Timer_A is a 16-bit timer/counter with multiple capture/compare registers. This chapter describes Timer_A. Timer_A3 (three capture/compare registers) is implemented in all MSP430x2xx devices, except for MSP430x20xx devices. Those devices implement Timer_A2 (two capture/compare registers).

Topic	Page
9.1 Timer_A Introduction	9-2
9.2 Timer_A Operation	9-4
9.3 Timer_A Registers	9-19

9.1 Timer_A Introduction

Timer_A is a 16-bit timer/counter with three capture/compare registers. Timer_A can support multiple capture/compares, PWM outputs, and interval timing. Timer_A also has extensive interrupt capabilities. Interrupts may be generated from the counter on overflow conditions and from each of the capture/compare registers.

Timer_A features include:

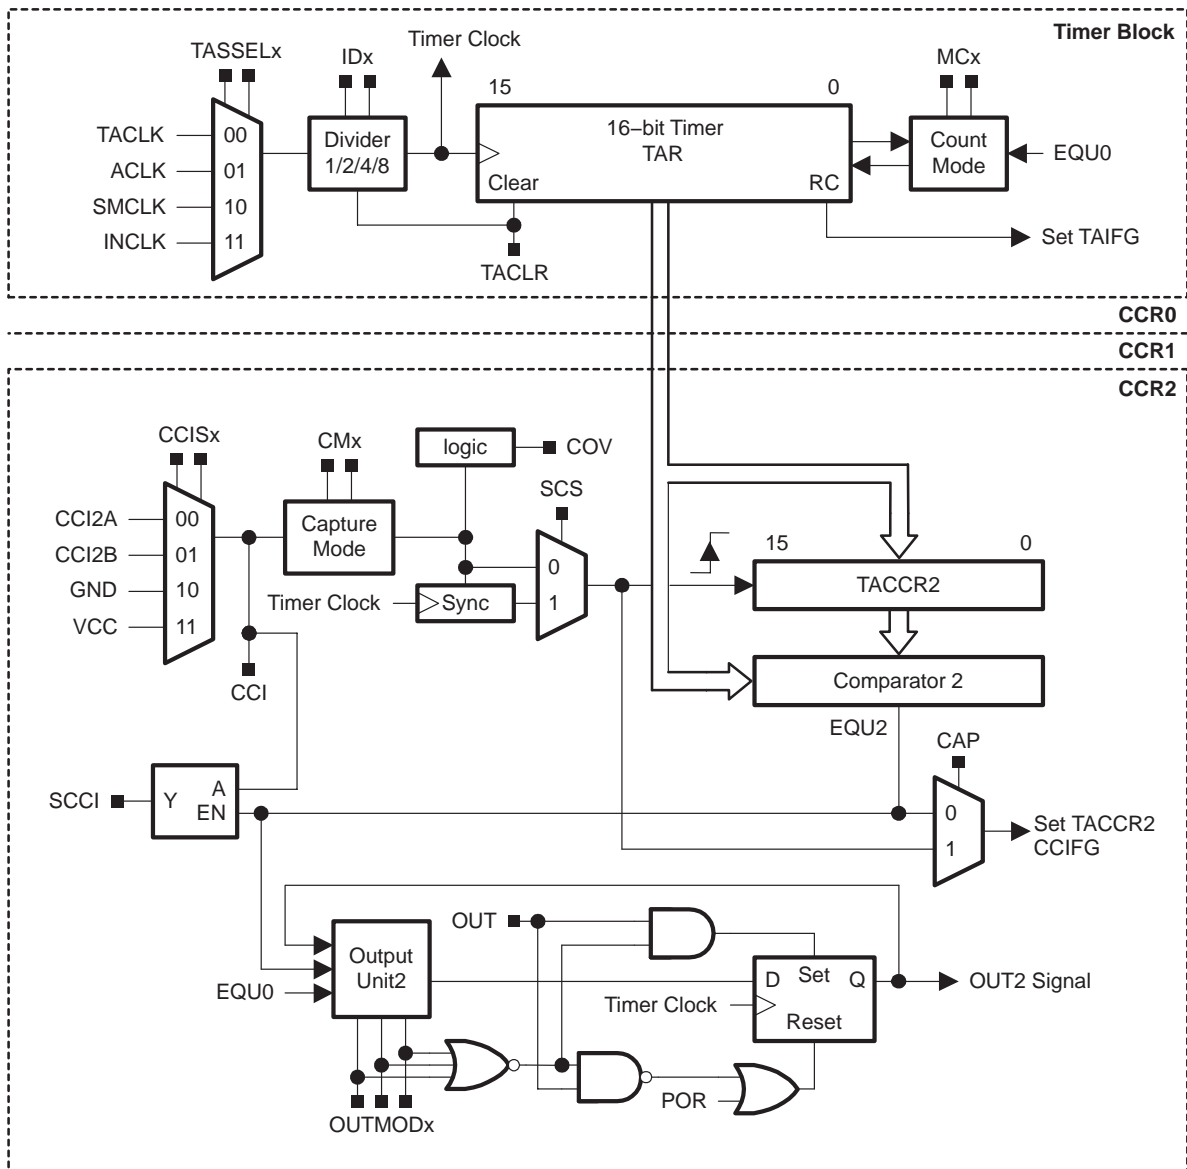

- ☐ Asynchronous 16-bit timer/counter with four operating modes
- ☐ Selectable and configurable clock source
- ☐ Two or Three configurable capture/compare registers
- ☐ Configurable outputs with PWM capability
- ☐ Asynchronous input and output latching
- ☐ Interrupt vector register for fast decoding of all Timer_A interrupts

The block diagram of Timer_A is shown in Figure 9–1.

Note: Use of the Word *Count*

Count is used throughout this chapter. It means the counter must be in the process of counting for the action to take place. If a particular value is directly written to the counter, then an associated action will not take place.

Figure 9–1. Timer_A Block Diagram

9.2 Timer_A Operation

The Timer_A module is configured with user software. The setup and operation of Timer_A is discussed in the following sections.

9.2.1 16-Bit Timer Counter

The 16-bit timer/counter register, TAR, increments or decrements (depending on mode of operation) with each rising edge of the clock signal. TAR can be read or written with software. Additionally, the timer can generate an interrupt when it overflows.

TAR may be cleared by setting the TACLR bit. Setting TACLR also clears the clock divider and count direction for up/down mode.

Note: Modifying Timer_A Registers

It is recommended to stop the timer before modifying its operation (with exception of the interrupt enable, interrupt flag, and TACLR) to avoid errant operating conditions.

When the timer clock is asynchronous to the CPU clock, any read from TAR should occur while the timer is not operating or the results may be unpredictable. Alternatively, the timer may be read multiple times while operating, and a majority vote taken in software to determine the correct reading. Any write to TAR will take effect immediately.

Clock Source Select and Divider

The timer clock can be sourced from ACLK, SMCLK, or externally via TACLK or INCLK. The clock source is selected with the TASSELx bits. The selected clock source may be passed directly to the timer or divided by 2, 4, or 8, using the IDx bits. The timer clock divider is reset when TACLR is set.

9.2.2 Starting the Timer

The timer may be started, or restarted in the following ways:

- ☐ The timer counts when MCx > 0 and the clock source is active.
- ☐ When the timer mode is either up or up/down, the timer may be stopped by writing 0 to TACCR0. The timer may then be restarted by writing a nonzero value to TACCR0. In this scenario, the timer starts incrementing in the up direction from zero.

9.2.3 Timer Mode Control

The timer has four modes of operation as described in Table 9–1: stop, up, continuous, and up/down. The operating mode is selected with the MCx bits.

Table 9–1. Timer Modes

MCx	Mode	Description
00	Stop	The timer is halted.
01	Up	The timer repeatedly counts from zero to the value of TACCR0
10	Continuous	The timer repeatedly counts from zero to 0FFFFh.
11	Up/down	The timer repeatedly counts from zero up to the value of TACCR0 and back down to zero.

Up Mode

The up mode is used if the timer period must be different from 0FFFFh counts. The timer repeatedly counts up to the value of compare register TACCR0, which defines the period, as shown in Figure 9–2. The number of timer counts in the period is TACCR0+1. When the timer value equals TACCR0 the timer restarts counting from zero. If up mode is selected when the timer value is greater than TACCR0, the timer immediately restarts counting from zero.

Figure 9–2. Up Mode

The TACCR0 CCIFG interrupt flag is set when the timer *counts* to the TACCR0 value. The TAIFG interrupt flag is set when the timer *counts* from TACCR0 to zero. Figure 9–3 shows the flag set cycle.

Figure 9–3. Up Mode Flag Setting

Changing the Period Register TACCR0

When changing TACCR0 while the timer is running, if the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period. If the new period is less than the current count value, the timer rolls to zero. However, one additional count may occur before the counter rolls to zero.

Continuous Mode

In the continuous mode, the timer repeatedly counts up to 0FFFFh and restarts from zero as shown in Figure 9–4. The capture/compare register TACCR0 works the same way as the other capture/compare registers.

Figure 9–4. Continuous Mode

The TAIFG interrupt flag is set when the timer *counts* from 0FFFFh to zero. Figure 9–5 shows the flag set cycle.

Figure 9–5. Continuous Mode Flag Setting

Use of the Continuous Mode

The continuous mode can be used to generate independent time intervals and output frequencies. Each time an interval is completed, an interrupt is generated. The next time interval is added to the TACCRx register in the interrupt service routine. Figure 9–6 shows two separate time intervals t_0 and t_1 being added to the capture/compare registers. In this usage, the time interval is controlled by hardware, not software, without impact from interrupt latency. Up to three independent time intervals or output frequencies can be generated using all three capture/compare registers.

Figure 9–6. Continuous Mode Time Intervals

Time intervals can be produced with other modes as well, where TACCR0 is used as the period register. Their handling is more complex since the sum of the old TACCRx data and the new period can be higher than the TACCR0 value. When the previous TACCRx value plus t_x is greater than the TACCR0 data, the TACCR0 value must be subtracted to obtain the correct time interval.

Up/Down Mode

The up/down mode is used if the timer period must be different from 0FFFFh counts, and if symmetrical pulse generation is needed. The timer repeatedly counts up to the value of compare register TACCR0 and back down to zero, as shown in Figure 9–7. The period is twice the value in TACCR0.

Figure 9–7. Up/Down Mode

The count direction is latched. This allows the timer to be stopped and then restarted in the same direction it was counting before it was stopped. If this is not desired, the TACLR bit must be set to clear the direction. The TACLR bit also clears the TAR value and the timer clock divider.

In up/down mode, the TACCR0 CCIFG interrupt flag and the TAIFG interrupt flag are set only once during a period, separated by 1/2 the timer period. The TACCR0 CCIFG interrupt flag is set when the timer *counts* from TACCR0–1 to TACCR0, and TAIFG is set when the timer completes *counting* down from 0001h to 0000h. Figure 9–8 shows the flag set cycle.

Figure 9–8. Up/Down Mode Flag Setting

Changing the Period Register TACCR0

When changing TACCR0 while the timer is running, and counting in the down direction, the timer continues its descent until it reaches zero. The new period takes affect after the counter counts down to zero.

When the timer is counting in the up direction, and the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period before counting down. When the timer is counting in the up direction, and the new period is less than the current count value, the timer begins counting down. However, one additional count may occur before the counter begins counting down.

Use of the Up/Down Mode

The up/down mode supports applications that require dead times between output signals (See section *Timer_A Output Unit*). For example, to avoid overload conditions, two outputs driving an H-bridge must never be in a high state simultaneously. In the example shown in Figure 9–9 the t_{dead} is:

$$t_{\text{dead}} = t_{\text{timer}} \times (\text{TACCR1} - \text{TACCR2})$$

With: t_{dead} Time during which both outputs need to be inactive

t_{timer} Cycle time of the timer clock

TACCRx Content of capture/compare register x

The TACCRx registers are not buffered. They update immediately when written to. Therefore, any required dead time will not be maintained automatically.

Figure 9–9. Output Unit in Up/Down Mode

9.2.4 Capture/Compare Blocks

Two or Three identical capture/compare blocks, TACCRx, are present in Timer_A. Any of the blocks may be used to capture the timer data, or to generate time intervals.

Capture Mode

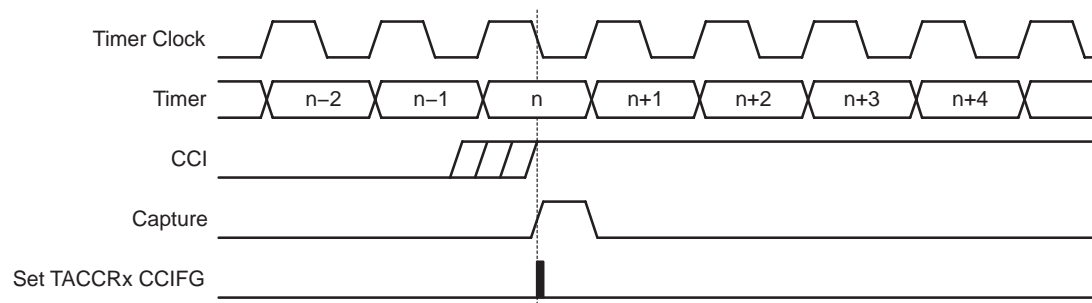

The capture mode is selected when CAP = 1. Capture mode is used to record time events. It can be used for speed computations or time measurements. The capture inputs CCIxA and CCIxB are connected to external pins or internal signals and are selected with the CCISx bits. The CMx bits select the capture edge of the input signal as rising, falling, or both. A capture occurs on the selected edge of the input signal. If a capture occurs:

- ☐ The timer value is copied into the TACCRx register
- ☐ The interrupt flag CCIFG is set

The input signal level can be read at any time via the CCI bit. MSP430x2xx family devices may have different signals connected to CCIxA and CCIxB. Refer to the device-specific datasheet for the connections of these signals.

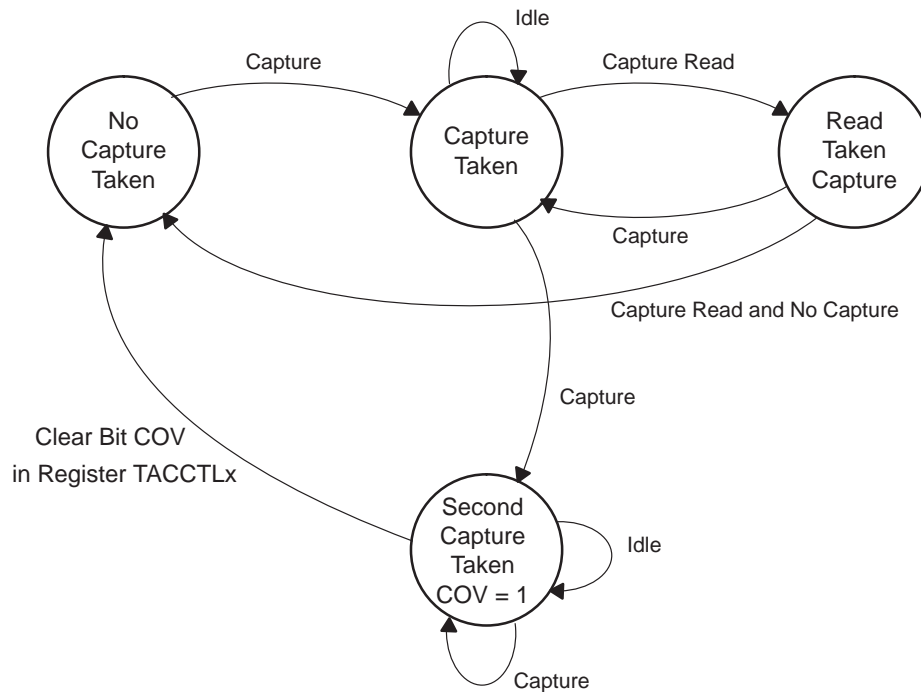

The capture signal can be asynchronous to the timer clock and cause a race condition. Setting the SCS bit will synchronize the capture with the next timer clock. Setting the SCS bit to synchronize the capture signal with the timer clock is recommended. This is illustrated in Figure 9–10.

Figure 9–10. Capture Signal (SCS=1)

Overflow logic is provided in each capture/compare register to indicate if a second capture was performed before the value from the first capture was read. Bit COV is set when this occurs as shown in Figure 9–11. COV must be reset with software.

Figure 9–11. Capture Cycle

Capture Initiated by Software

Captures can be initiated by software. The CMx bits can be set for capture on both edges. Software then sets CCIS1 = 1 and toggles bit CCIS0 to switch the capture signal between V_{CC} and GND, initiating a capture each time CCIS0 changes state:

```

MOV    #CAP+SCS+CCIS1+CM_3,&TACCTLx ; Setup TACCTLx
XOR    #CCIS0,&TACCTLx                ; TACCTLx = TAR
  
```

Compare Mode

The compare mode is selected when CAP = 0. The compare mode is used to generate PWM output signals or interrupts at specific time intervals. When TAR *counts* to the value in a TACCRx:

- ☐ Interrupt flag CCIFG is set
- ☐ Internal signal EQUx = 1
- ☐ EQUx affects the output according to the output mode
- ☐ The input signal CCI is latched into SCCI

9.2.5 Output Unit

Each capture/compare block contains an output unit. The output unit is used to generate output signals such as PWM signals. Each output unit has eight operating modes that generate signals based on the EQU0 and EQUx signals.

Output Modes

The output modes are defined by the OUTMODx bits and are described in Table 9–2. The OUTx signal is changed with the rising edge of the timer clock for all modes except mode 0. Output modes 2, 3, 6, and 7 are not useful for output unit 0 because EQUx = EQU0.

Table 9–2. Output Modes

OUTMODx	Mode	Description
000	Output	The output signal OUTx is defined by the OUTx bit. The OUTx signal updates immediately when OUTx is updated.
001	Set	The output is set when the timer <i>counts</i> to the TACCRx value. It remains set until a reset of the timer, or until another output mode is selected and affects the output.
010	Toggle/Reset	The output is toggled when the timer <i>counts</i> to the TACCRx value. It is reset when the timer <i>counts</i> to the TACCR0 value.
011	Set/Reset	The output is set when the timer <i>counts</i> to the TACCRx value. It is reset when the timer <i>counts</i> to the TACCR0 value.
100	Toggle	The output is toggled when the timer <i>counts</i> to the TACCRx value. The output period is double the timer period.
101	Reset	The output is reset when the timer <i>counts</i> to the TACCRx value. It remains reset until another output mode is selected and affects the output.
110	Toggle/Set	The output is toggled when the timer <i>counts</i> to the TACCRx value. It is set when the timer <i>counts</i> to the TACCR0 value.
111	Reset/Set	The output is reset when the timer <i>counts</i> to the TACCRx value. It is set when the timer <i>counts</i> to the TACCR0 value.

Output Example—Timer in Up Mode

The OUTx signal is changed when the timer *counts* up to the TACCRx value, and rolls from TACCR0 to zero, depending on the output mode. An example is shown in Figure 9–12 using TACCR0 and TACCR1.

Figure 9–12. Output Example—Timer in Up Mode

Output Example—Timer in Continuous Mode

The OUTx signal is changed when the timer reaches the TACCRx and TACCR0 values, depending on the output mode. An example is shown in Figure 9–13 using TACCR0 and TACCR1.

Figure 9–13. Output Example—Timer in Continuous Mode

Output Example—Timer in Up/Down Mode

The OUTx signal changes when the timer equals TACCRx in either count direction and when the timer equals TACCR0, depending on the output mode. An example is shown in Figure 9–14 using TACCR0 and TACCR2.

Figure 9–14. Output Example—Timer in Up/Down Mode

**Note: Switching Between Output Modes**

When switching between output modes, one of the OUTMODx bits should remain set during the transition, unless switching to mode 0. Otherwise, output glitching can occur because a NOR gate decodes output mode 0. A safe method for switching between output modes is to use output mode 7 as a transition state:

```
BIS    #OUTMOD_7,&TACCTLx ; Set output mode=7
BIC    #OUTMODx,&TACCTLx  ; Clear unwanted bits
```

9.2.6 Timer_A Interrupts

Two interrupt vectors are associated with the 16-bit Timer_A module:

- ☐ TACCR0 interrupt vector for TACCR0 CCIFG
- ☐ TAIV interrupt vector for all other CCIFG flags and TAIFG

In capture mode any CCIFG flag is set when a timer value is captured in the associated TACCRx register. In compare mode, any CCIFG flag is set if TAR *counts* to the associated TACCRx value. Software may also set or clear any CCIFG flag. All CCIFG flags request an interrupt when their corresponding CCIE bit and the GIE bit are set.

TACCR0 Interrupt

The TACCR0 CCIFG flag has the highest Timer_A interrupt priority and has a dedicated interrupt vector as shown in Figure 9–15. The TACCR0 CCIFG flag is automatically reset when the TACCR0 interrupt request is serviced.

Figure 9–15. Capture/Compare TACCR0 Interrupt Flag

TAIV, Interrupt Vector Generator

The TACCR1 CCIFG, TACCR2 CCIFG, and TAIFG flags are prioritized and combined to source a single interrupt vector. The interrupt vector register TAIV is used to determine which flag requested an interrupt.

The highest priority enabled interrupt generates a number in the TAIV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled Timer_A interrupts do not affect the TAIV value.

Any access, read or write, of the TAIV register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt. For example, if the TACCR1 and TACCR2 CCIFG flags are set when the interrupt service routine accesses the TAIV register, TACCR1 CCIFG is reset automatically. After the RETI instruction of the interrupt service routine is executed, the TACCR2 CCIFG flag will generate another interrupt.

TAIV Software Example

The following software example shows the recommended use of TAIV and the handling overhead. The TAIV value is added to the PC to automatically jump to the appropriate routine.

The numbers at the right margin show the necessary CPU cycles for each instruction. The software overhead for different interrupt sources includes interrupt latency and return-from-interrupt cycles, but not the task handling itself. The latencies are:

<input type="checkbox"/> Capture/compare block TACCR0	11 cycles
<input type="checkbox"/> Capture/compare blocks TACCR1, TACCR2	16 cycles
<input type="checkbox"/> Timer overflow TAIFG	14 cycles

```

Timer_B

Timer_B is a 16-bit timer/counter with multiple capture/compare registers. This chapter describes Timer_B. Timer_B3 (three capture/compare registers) is implemented in MSP430x22x4 devices.

Topic	Page
10.1 Timer_B Introduction	10-2
10.2 Timer_B Operation	10-4
10.3 Timer_B Registers	10-20

10.1 Timer_B Introduction

Timer_B is a 16-bit timer/counter with three or seven capture/compare registers. Timer_B can support multiple capture/compares, PWM outputs, and interval timing. Timer_B also has extensive interrupt capabilities. Interrupts may be generated from the counter on overflow conditions and from each of the capture/compare registers.

Timer_B features include :

- ☐ Asynchronous 16-bit timer/counter with four operating modes and four selectable lengths
- ☐ Selectable and configurable clock source
- ☐ Three or seven configurable capture/compare registers
- ☐ Configurable outputs with PWM capability
- ☐ Double-buffered compare latches with synchronized loading
- ☐ Interrupt vector register for fast decoding of all Timer_B interrupts

The block diagram of Timer_B is shown in Figure 10–1.

Note: Use of the Word *Count*

Count is used throughout this chapter. It means the counter must be in the process of counting for the action to take place. If a particular value is directly written to the counter, then an associated action does not take place.

10.1.1 Similarities and Differences From Timer_A

Timer_B is identical to Timer_A with the following exceptions:

- ☐ The length of Timer_B is programmable to be 8, 10, 12, or 16 bits.
- ☐ Timer_B TBCCR_x registers are double-buffered and can be grouped.
- ☐ All Timer_B outputs can be put into a high-impedance state.
- ☐ The SCCI bit function is not implemented in Timer_B.

Figure 10–1. Timer_B Block Diagram

10.2 Timer_B Operation

The Timer_B module is configured with user software. The setup and operation of Timer_B is discussed in the following sections.

10.2.1 16-Bit Timer Counter

The 16-bit timer/counter register, TBR, increments or decrements (depending on mode of operation) with each rising edge of the clock signal. TBR can be read or written with software. Additionally, the timer can generate an interrupt when it overflows.

TBR may be cleared by setting the TBCLR bit. Setting TBCLR also clears the clock divider and count direction for up/down mode.

Note: Modifying Timer_B Registers

It is recommended to stop the timer before modifying its operation (with exception of the interrupt enable, interrupt flag, and TBCLR) to avoid errant operating conditions.

When the timer clock is asynchronous to the CPU clock, any read from TBR should occur while the timer is not operating or the results may be unpredictable. Alternatively, the timer may be read multiple times while operating, and a majority vote taken in software to determine the correct reading. Any write to TBR will take effect immediately.

TBR Length

Timer_B is configurable to operate as an 8-, 10-, 12-, or 16-bit timer with the CNTLx bits. The maximum count value, $TBR_{(max)}$, for the selectable lengths is 0FFh, 03FFh, 0FFFh, and 0FFFFh, respectively. Data written to the TBR register in 8-, 10-, and 12-bit mode is right-justified with leading zeros.

Clock Source Select and Divider

The timer clock can be sourced from ACLK, SMCLK, or externally via TBCLK or INCLK. The clock source is selected with the TBSSELx bits. The selected clock source may be passed directly to the timer or divided by 2, 4, or 8, using the IDx bits. The clock divider is reset when TBCLR is set.

10.2.2 Starting the Timer

The timer may be started or restarted in the following ways:

- ☐ The timer counts when MCx > 0 and the clock source is active.
- ☐ When the timer mode is either up or up/down, the timer may be stopped by loading 0 to TBCL0. The timer may then be restarted by loading a nonzero value to TBCL0. In this scenario, the timer starts incrementing in the up direction from zero.

10.2.3 Timer Mode Control

The timer has four modes of operation as described in Table 10–1: stop, up, continuous, and up/down. The operating mode is selected with the MCx bits.

Table 10–1. Timer Modes

MCx	Mode	Description
00	Stop	The timer is halted.
01	Up	The timer repeatedly counts from zero to the value of compare register TBCL0.
10	Continuous	The timer repeatedly counts from zero to the value selected by the TBCNTLx bits.
11	Up/down	The timer repeatedly counts from zero up to the value of TBCL0 and then back down to zero.

Up Mode

The up mode is used if the timer period must be different from $TBR_{(max)}$ counts. The timer repeatedly counts up to the value of compare latch TBCL0, which defines the period, as shown in Figure 10–2. The number of timer counts in the period is TBCL0+1. When the timer value equals TBCL0 the timer restarts counting from zero. If up mode is selected when the timer value is greater than TBCL0, the timer immediately restarts counting from zero.

Figure 10–2. Up Mode

The TBCCR0 CCIFG interrupt flag is set when the timer *counts* to the TBCL0 value. The TBIFG interrupt flag is set when the timer *counts* from TBCL0 to zero. Figure 10–3 shows the flag set cycle.

Figure 10–3. Up Mode Flag Setting

Changing the Period Register TBCL0

When changing TBCL0 while the timer is running and when the TBCL0 load mode is *immediate*, if the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period. If the new period is less than the current count value, the timer rolls to zero. However, one additional count may occur before the counter rolls to zero.

Continuous Mode

In continuous mode the timer repeatedly counts up to $TBR_{(max)}$ and restarts from zero as shown in Figure 10–4. The compare latch TBCL0 works the same way as the other capture/compare registers.

Figure 10–4. Continuous Mode

The TBIFG interrupt flag is set when the timer *counts* from $TBR_{(max)}$ to zero. Figure 10–5 shows the flag set cycle.

Figure 10–5. Continuous Mode Flag Setting

Use of the Continuous Mode

The continuous mode can be used to generate independent time intervals and output frequencies. Each time an interval is completed, an interrupt is generated. The next time interval is added to the TBCLx latch in the interrupt service routine. Figure 10–6 shows two separate time intervals t_0 and t_1 being added to the capture/compare registers. The time interval is controlled by hardware, not software, without impact from interrupt latency. Up to three (Timer_B3) or 7 (Timer_B7) independent time intervals or output frequencies can be generated using capture/compare registers.

Figure 10–6. Continuous Mode Time Intervals

Time intervals can be produced with other modes as well, where TBCL0 is used as the period register. Their handling is more complex since the sum of the old TBCLx data and the new period can be higher than the TBCL0 value. When the sum of the previous TBCLx value plus t_x is greater than the TBCL0 data, the old TBCL0 value must be subtracted to obtain the correct time interval.

Up/Down Mode

The up/down mode is used if the timer period must be different from $TBR_{(max)}$ counts, and if symmetrical pulse generation is needed. The timer repeatedly counts up to the value of compare latch TBCL0, and back down to zero, as shown in Figure 10–7. The period is twice the value in TBCL0.

Note: $TBCL0 > TBR_{(max)}$

If $TBCL0 > TBR_{(max)}$, the counter operates as if it were configured for continuous mode. It does not count down from $TBR_{(max)}$ to zero.

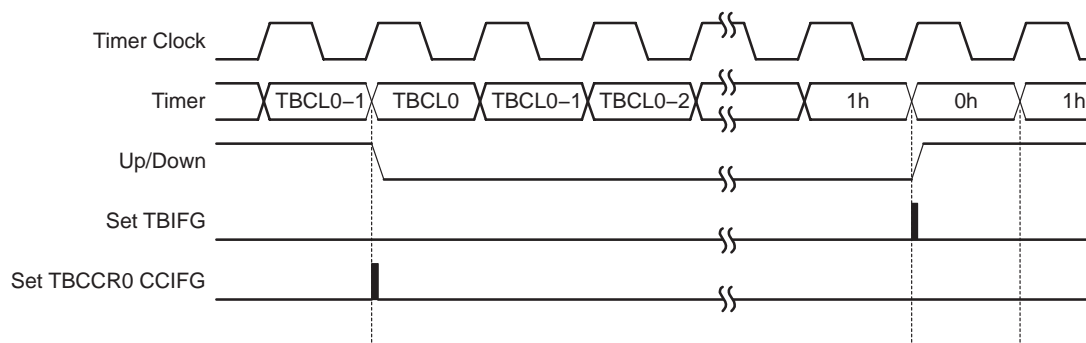

Figure 10–7. Up/Down Mode

The count direction is latched. This allows the timer to be stopped and then restarted in the same direction it was counting before it was stopped. If this is not desired, the TBCLR bit must be used to clear the direction. The TBCLR bit also clears the TBR value and the clock divider.

In up/down mode, the TBCCR0 CCIFG interrupt flag and the TBIFG interrupt flag are set only once during the period, separated by 1/2 the timer period. The TBCCR0 CCIFG interrupt flag is set when the timer *counts* from $TBCL0-1$ to $TBCL0$, and TBIFG is set when the timer completes *counting* down from 0001h to 0000h. Figure 10–8 shows the flag set cycle.

Figure 10–8. Up/Down Mode Flag Setting

Changing the Value of Period Register TBCL0

When changing TBCL0 while the timer is running, and counting in the down direction, and when the TBCL0 load mode is *immediate*, the timer continues its descent until it reaches zero. The new period takes effect after the counter counts down to zero.

If the timer is counting in the up direction when the new period is latched into TBCL0, and the new period is greater than or equal to the old period, or greater than the current count value, the timer counts up to the new period before counting down. When the timer is counting in the up direction, and the new period is less than the current count value when TBCL0 is loaded, the timer begins counting down. However, one additional count may occur before the counter begins counting down.

Use of the Up/Down Mode

The up/down mode supports applications that require dead times between output signals (see section *Timer_B Output Unit*). For example, to avoid overload conditions, two outputs driving an H-bridge must never be in a high state simultaneously. In the example shown in Figure 10–9 the t_{dead} is:

$$t_{\text{dead}} = t_{\text{timer}} \times (\text{TBCL1} - \text{TBCL3})$$

With: t_{dead} Time during which both outputs need to be inactive

t_{timer} Cycle time of the timer clock

TBCLx Content of compare latch x

The ability to simultaneously load grouped compare latches assures the dead times.

Figure 10–9. Output Unit in Up/Down Mode

10.2.4 Capture/Compare Blocks

Three or seven identical capture/compare blocks, TBCCR_x, are present in Timer_B. Any of the blocks may be used to capture the timer data or to generate time intervals.

Capture Mode

The capture mode is selected when CAP = 1. Capture mode is used to record time events. It can be used for speed computations or time measurements. The capture inputs CCI_xA and CCI_xB are connected to external pins or internal signals and are selected with the CCIS_x bits. The CM_x bits select the capture edge of the input signal as rising, falling, or both. A capture occurs on the selected edge of the input signal. If a capture is performed:

- ☐ The timer value is copied into the TBCCR_x register
- ☐ The interrupt flag CCIFG is set

The input signal level can be read at any time via the CCI bit. MSP430x2xx family devices may have different signals connected to CCI_xA and CCI_xB. Refer to the device-specific datasheet for the connections of these signals.

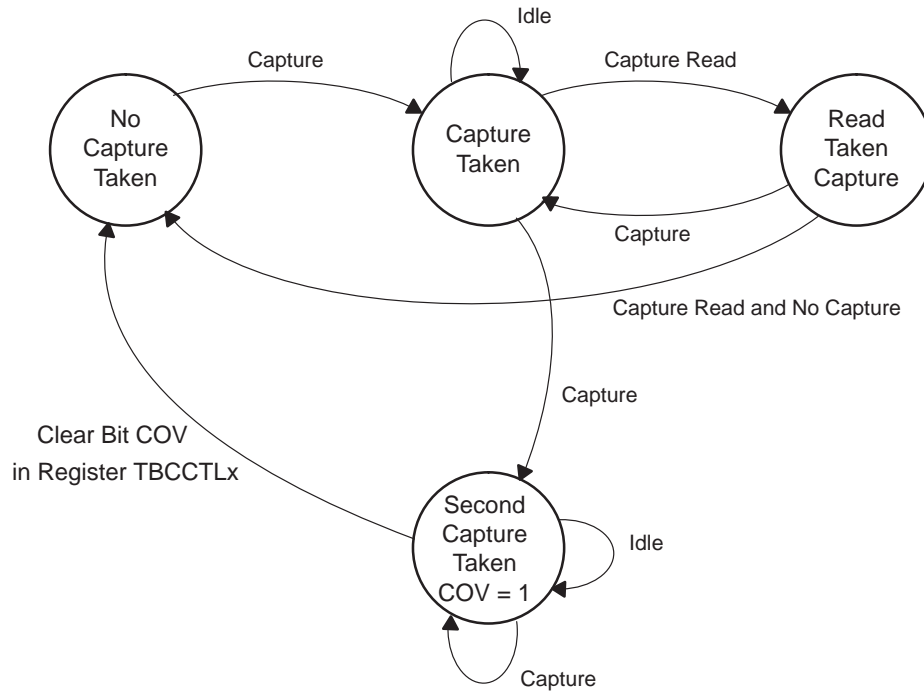

The capture signal can be asynchronous to the timer clock and cause a race condition. Setting the SCS bit will synchronize the capture with the next timer clock. Setting the SCS bit to synchronize the capture signal with the timer clock is recommended. This is illustrated in Figure 10–10.

Figure 10–10. Capture Signal (SCS=1)

Overflow logic is provided in each capture/compare register to indicate if a second capture was performed before the value from the first capture was read. Bit COV is set when this occurs as shown in Figure 10–11. COV must be reset with software.

Figure 10–11. Capture Cycle

Capture Initiated by Software

Captures can be initiated by software. The CMx bits can be set for capture on both edges. Software then sets bit CCIS1=1 and toggles bit CCIS0 to switch the capture signal between V_{CC} and GND, initiating a capture each time CCIS0 changes state:

```

MOV    #CAP+SCS+CCIS1+CM_3,&TBCCTLx ; Setup TBCCTLx
XOR    #CCIS0,&TBCCTLx                ; TBCCTLx = TBR

```

Compare Mode

The compare mode is selected when CAP = 0. Compare mode is used to generate PWM output signals or interrupts at specific time intervals. When TBR *counts* to the value in a TBCLx:

- ☐ Interrupt flag CCIFG is set
- ☐ Internal signal EQUx = 1
- ☐ EQUx affects the output according to the output mode

Compare Latch TBCLx

The TBCCR_x compare latch, TBCL_x, holds the data for the comparison to the timer value in compare mode. TBCL_x is buffered by TBCCR_x. The buffered compare latch gives the user control over when a compare period updates. The user cannot directly access TBCL_x. Compare data is written to each TBCCR_x and automatically transferred to TBCL_x. The timing of the transfer from TBCCR_x to TBCL_x is user-selectable with the CLLD_x bits as described in Table 10–2.

Table 10–2. TBCL_x Load Events

CLLD _x	Description
00	New data is transferred from TBCCR _x to TBCL _x immediately when TBCCR _x is written to.
01	New data is transferred from TBCCR _x to TBCL _x when TBR <i>counts</i> to 0
10	New data is transferred from TBCCR _x to TBCL _x when TBR <i>counts</i> to 0 for up and continuous modes. New data is transferred to from TBCCR _x to TBCL _x when TBR <i>counts</i> to the old TBCL ₀ value or to 0 for up/down mode
11	New data is transferred from TBCCR _x to TBCL _x when TBR <i>counts</i> to the old TBCL _x value.

Grouping Compare Latches

Multiple compare latches may be grouped together for simultaneous updates with the TBCLGRP_x bits. When using groups, the CLLD_x bits of the lowest numbered TBCCR_x in the group determine the load event for each compare latch of the group, except when TBCLGRP = 3, as shown in Table 10–3. The CLLD_x bits of the controlling TBCCR_x must not be set to zero. When the CLLD_x bits of the controlling TBCCR_x are set to zero, all compare latches update immediately when their corresponding TBCCR_x is written - no compare latches are grouped.

Two conditions must exist for the compare latches to be loaded when grouped. First, all TBCCR_x registers of the group must be updated, even when new TBCCR_x data = old TBCCR_x data. Second, the load event must occur.

Table 10–3. Compare Latch Operating Modes

TBCLGRP _x	Grouping	Update Control
00	None	Individual
01	TBCL1+TBCL2 TBCL3+TBCL4 TBCL5+TBCL6	TBCCR1 TBCCR3 TBCCR5
10	TBCL1+TBCL2+TBCL3 TBCL4+TBCL5+TBCL6	TBCCR1 TBCCR4
11	TBCL0+TBCL1+TBCL2+ TBCL3+TBCL4+TBCL5+TBCL6	TBCCR1

10.2.5 Output Unit

Each capture/compare block contains an output unit. The output unit is used to generate output signals such as PWM signals. Each output unit has eight operating modes that generate signals based on the EQU0 and EQUx signals. The TBOUTH pin function can be used to put all Timer_B outputs into a high-impedance state. When the TBOUTH pin function is selected for the pin, and when the pin is pulled high, all Timer_B outputs are in a high-impedance state.

Output Modes

The output modes are defined by the OUTMODx bits and are described in Table 10–4. The OUTx signal is changed with the rising edge of the timer clock for all modes except mode 0. Output modes 2, 3, 6, and 7 are not useful for output unit 0 because EQUx = EQU0.

Table 10–4. Output Modes

OUTMODx	Mode	Description
000	Output	The output signal OUTx is defined by the OUTx bit. The OUTx signal updates immediately when OUTx is updated.
001	Set	The output is set when the timer <i>counts</i> to the TBCLx value. It remains set until a reset of the timer, or until another output mode is selected and affects the output.
010	Toggle/Reset	The output is toggled when the timer <i>counts</i> to the TBCLx value. It is reset when the timer <i>counts</i> to the TBCL0 value.
011	Set/Reset	The output is set when the timer <i>counts</i> to the TBCLx value. It is reset when the timer <i>counts</i> to the TBCL0 value.
100	Toggle	The output is toggled when the timer <i>counts</i> to the TBCLx value. The output period is double the timer period.
101	Reset	The output is reset when the timer <i>counts</i> to the TBCLx value. It remains reset until another output mode is selected and affects the output.
110	Toggle/Set	The output is toggled when the timer <i>counts</i> to the TBCLx value. It is set when the timer <i>counts</i> to the TBCL0 value.
111	Reset/Set	The output is reset when the timer <i>counts</i> to the TBCLx value. It is set when the timer <i>counts</i> to the TBCL0 value.

Output Example—Timer in Up Mode

The OUTx signal is changed when the timer *counts* up to the TBCLx value, and rolls from TBCL0 to zero, depending on the output mode. An example is shown in Figure 10–12 using TBCL0 and TBCL1.

Figure 10–12. Output Example—Timer in Up Mode

Output Example—Timer in Continuous Mode

The OUTx signal is changed when the timer reaches the TBCLx and TBCL0 values, depending on the output mode. An example is shown in Figure 10–13 using TBCL0 and TBCL1.

Figure 10–13. Output Example—Timer in Continuous Mode

Output Example – Timer in Up/Down Mode

The OUTx signal changes when the timer equals TBCLx in either count direction and when the timer equals TBCL0, depending on the output mode. An example is shown in Figure 10–14 using TBCL0 and TBCL3.

Figure 10–14. Output Example—Timer in Up/Down Mode

**Note: Switching Between Output Modes**

When switching between output modes, one of the OUTMODx bits should remain set during the transition, unless switching to mode 0. Otherwise, output glitching can occur because a NOR gate decodes output mode 0. A safe method for switching between output modes is to use output mode 7 as a transition state:

```
BIS    #OUTMOD_7,&TBCCTLx ; Set output mode=7
BIC    #OUTMODx,&TBCCTLx  ; Clear unwanted bits
```

10.2.6 Timer_B Interrupts

Two interrupt vectors are associated with the 16-bit Timer_B module:

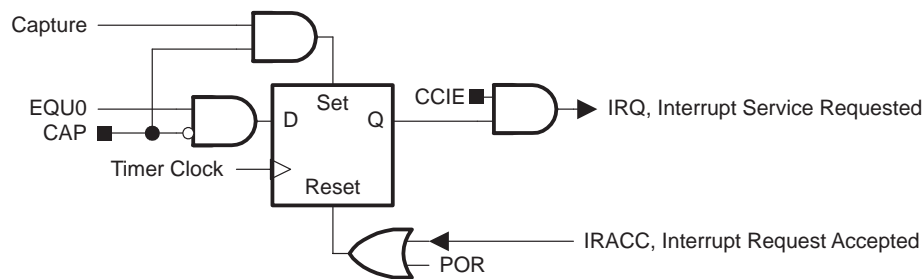

- TBCCR0 interrupt vector for TBCCR0 CCIFG
- TBIV interrupt vector for all other CCIFG flags and TBIFG

In capture mode, any CCIFG flag is set when a timer value is captured in the associated TBCCR_x register. In compare mode, any CCIFG flag is set when TBR *counts* to the associated TBCL_x value. Software may also set or clear any CCIFG flag. All CCIFG flags request an interrupt when their corresponding CCIE bit and the GIE bit are set.

TBCCR0 Interrupt Vector

The TBCCR0 CCIFG flag has the highest Timer_B interrupt priority and has a dedicated interrupt vector as shown in Figure 10–15. The TBCCR0 CCIFG flag is automatically reset when the TBCCR0 interrupt request is serviced.

Figure 10–15. Capture/Compare TBCCR0 Interrupt Flag

TBIV, Interrupt Vector Generator

The TBIFG flag and TBCCR_x CCIFG flags (excluding TBCCR0 CCIFG) are prioritized and combined to source a single interrupt vector. The interrupt vector register TBIV is used to determine which flag requested an interrupt.

The highest priority enabled interrupt (excluding TBCCR0 CCIFG) generates a number in the TBIV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled Timer_B interrupts do not affect the TBIV value.

Any access, read or write, of the TBIV register automatically resets the highest pending interrupt flag. If another interrupt flag is set, another interrupt is immediately generated after servicing the initial interrupt. For example, if the TBCCR1 and TBCCR2 CCIFG flags are set when the interrupt service routine accesses the TBIV register, TBCCR1 CCIFG is reset automatically. After the RETI instruction of the interrupt service routine is executed, the TBCCR2 CCIFG flag will generate another interrupt.

TBIV, Interrupt Handler Examples

The following software example shows the recommended use of TBIV and the handling overhead. The TBIV value is added to the PC to automatically jump to the appropriate routine.

The numbers at the right margin show the necessary CPU clock cycles for each instruction. The software overhead for different interrupt sources includes interrupt latency and return-from-interrupt cycles, but not the task handling itself. The latencies are:

<input type="checkbox"/> Capture/compare block CCR0	11 cycles
<input type="checkbox"/> Capture/compare blocks CCR1 to CCR6	16 cycles
<input type="checkbox"/> Timer overflow TBIFG	14 cycles

The following software example shows the recommended use of TBIV for Timer_B3.

```

; Interrupt handler for TBCCR0 CCIFG.                                Cycles
CCIFG_0_HND

Universal Serial Interface

The Universal Serial Interface (USI) module provides SPI and I²C serial communication with one hardware module. This chapter discusses both modes. The USI module is implemented in the MSP430x20xx devices.

Topic	Page
11.1 USI Introduction	11-2
11.2 USI Operation	11-5
11.3 USI Registers	11-13

11.1 USI Introduction

The USI module provides the basic functionality to support synchronous serial communication. In its simplest form, it is an 8- or 16-bit shift register that can be used to output data streams, or when combined with minimal software, can implement serial communication. In addition, the USI includes built-in hardware functionality to ease the implementation of SPI and I²C communication. The USI module also includes interrupts to further reduce the necessary software overhead for serial communication and to maintain the ultralow-power capabilities of the MSP430.

The USI module features include:

- ☐ Three-wire SPI mode support
- ☐ I²C mode support
- ☐ Variable data length
- ☐ Slave operation in LPM4 – no internal clock required
- ☐ Selectable MSB or LSB data order
- ☐ START and STOP detection for I²C mode with automatic SCL control
- ☐ Arbitration lost detection in master mode
- ☐ Programmable clock generation
- ☐ Selectable clock polarity and phase control

Figure 11–1 shows the USI module in SPI mode. Figure 11–2 shows the USI module in I²C mode.

Figure 11–1. USI Block Diagram: SPI Mode

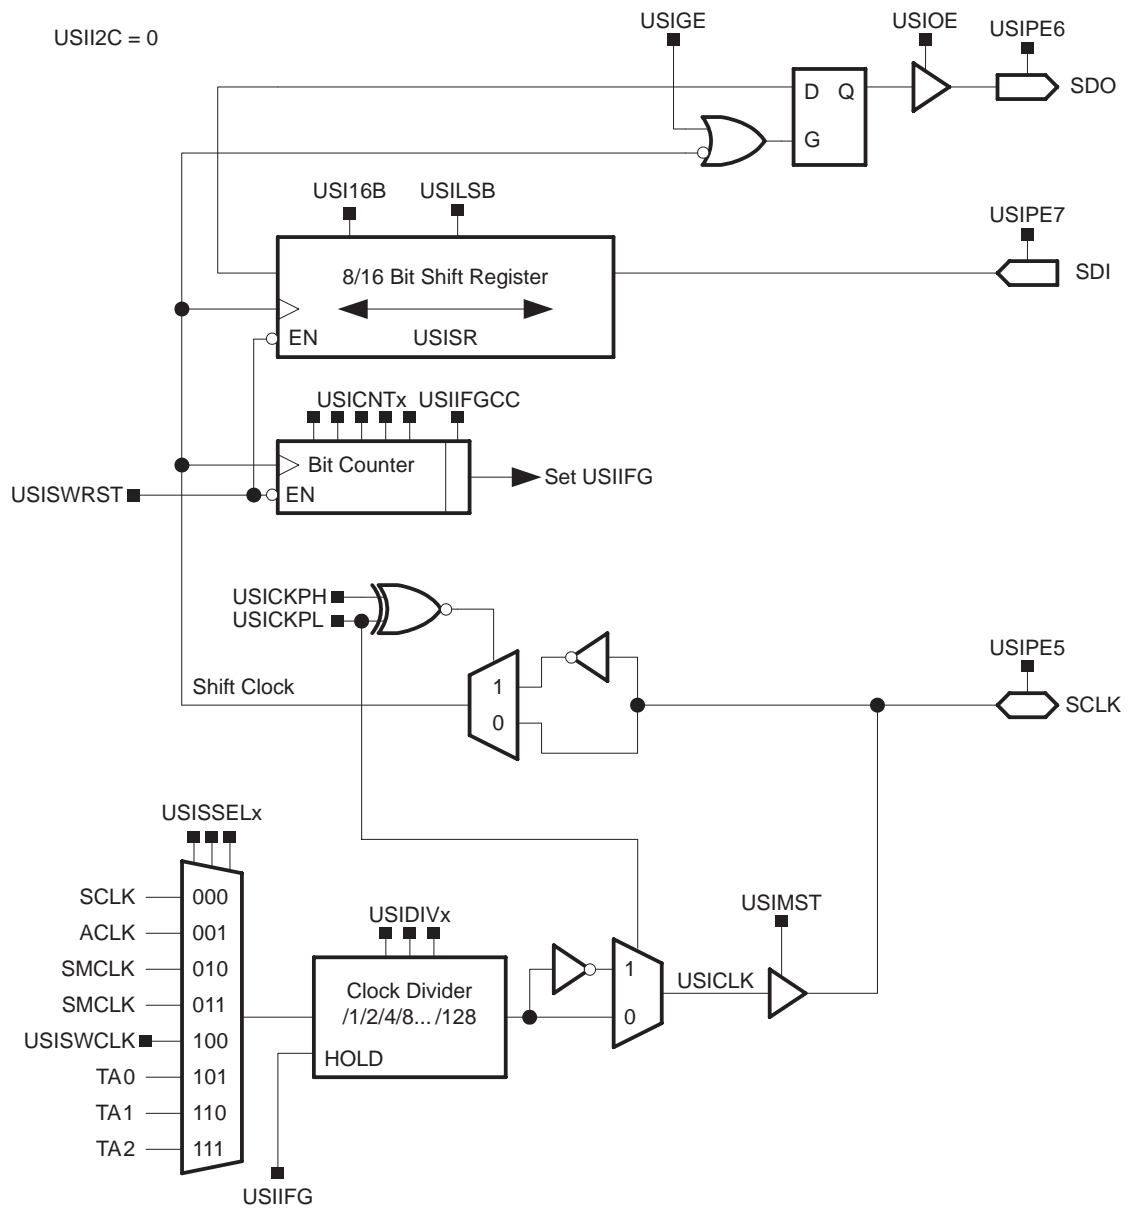

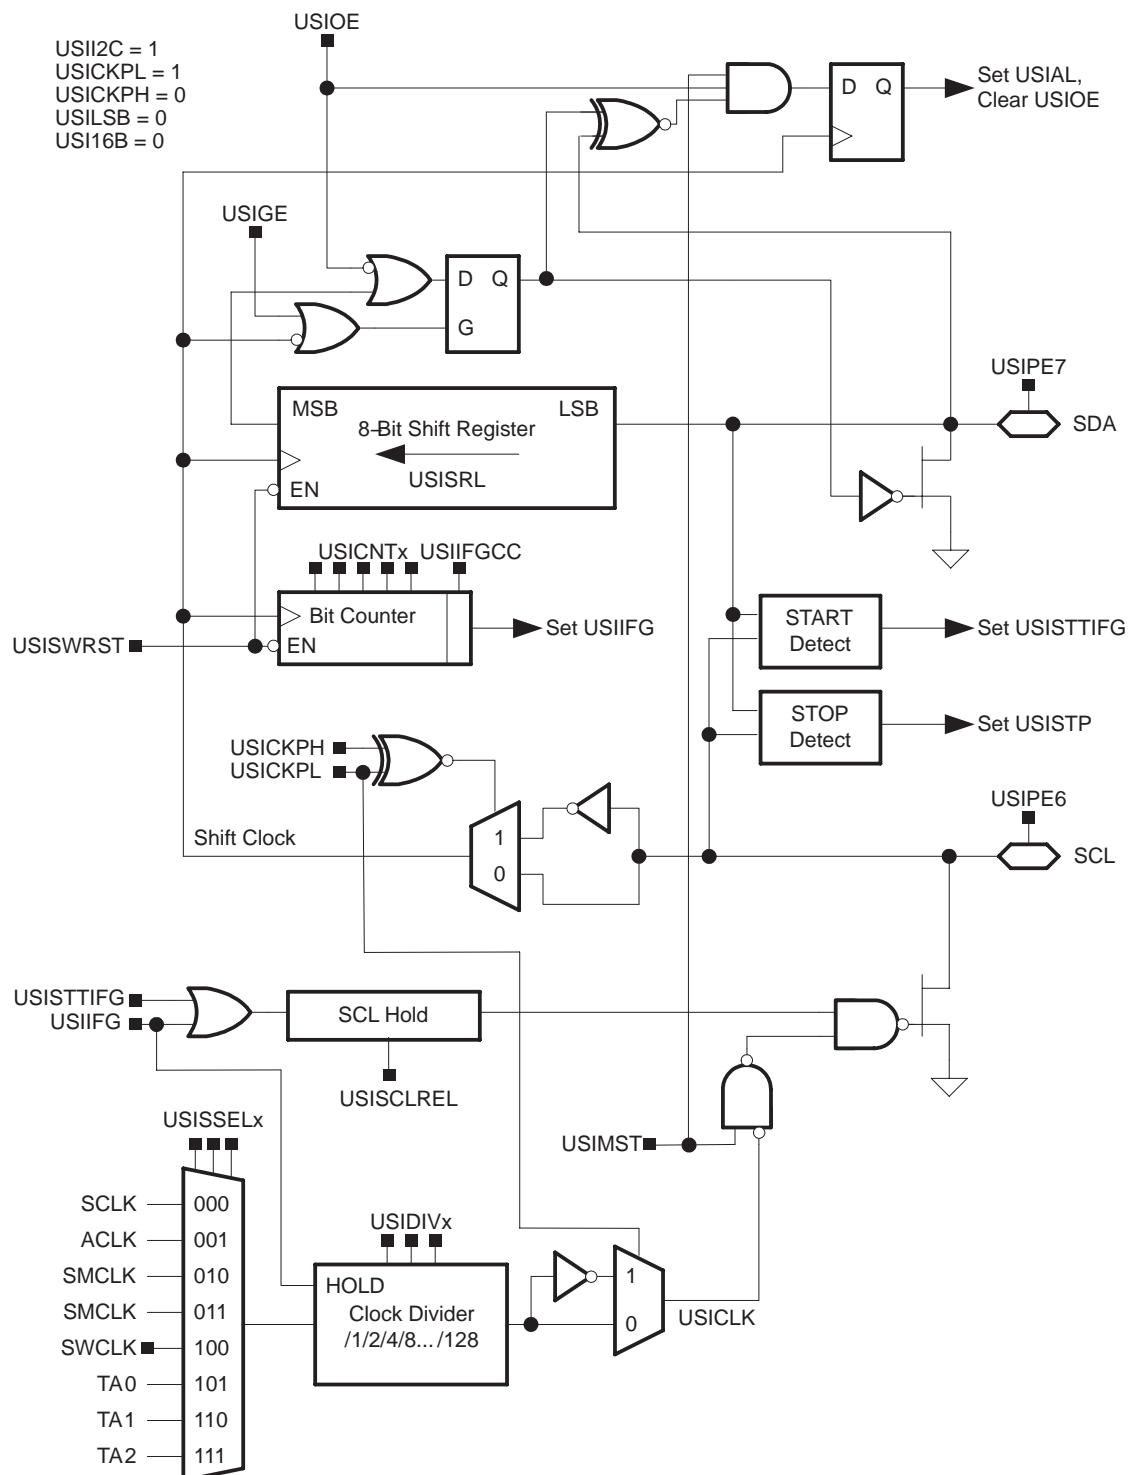

Figure 11-2. USI Block Diagram: I2C Mode

11.2 USI Operation

The USI module is a shift register and bit counter that includes logic to support SPI and I²C communication. The USI shift register, USISR, is directly accessible by software and contains the data to be transmitted or the data that has been received.

The bit counter counts the number of sampled bits and sets the USI interrupt flag USIIFG when the USICNTx value becomes zero - either by decrementing or by directly writing zero to the USICNTx bits. Writing USICNTx with a value > 0 automatically clears USIIFG when USIIFGCC = 0, otherwise USIIFG is not affected. The USICNTx bits stop decrementing when they become 0. They will not underflow to 0FFh.

Both the counter and the shift register are driven by the same shift clock. On a rising shift clock edge, USICNTx decrements and USISR samples the next bit input. The latch connected to the shift register's output delays the change of the output to the falling edge of shift clock. It can be made transparent by setting the USIGE bit. This setting will immediately output the MSB or LSB of USISR to the SDO pin, depending on the USILSB bit.

11.2.1 USI Initialization

While the USI software reset bit, USISWRST, is set, the flags USIIFG, USISTTIFG, USISTP, and USIAL will be held in their reset state. USISR and USICNTx are not clocked and their contents are not affected. In I²C mode, the SCL line is also released to the idle state by the USI hardware.

To activate USI port functionality the corresponding USIPEx bits in the USI control register must be set. This will select the USI function for the pin and maintains the PxIN and PxIFG functions for the pin as well. With this feature, the port input levels can be read via the PxIN register by software and the incoming data stream can generate port interrupts on data transitions. This is useful, for example, to generate a port interrupt on a START edge.

11.2.2 USI Clock Generation

The USI clock generator contains a clock selection multiplexer, a divider, and the ability to select the clock polarity as shown in the block diagrams Figure 11–1 and Figure 11–2.

The clock source can be selected from the internal clocks ACLK or SMCLK, from an external clock SCLK, as well as from the capture/compare outputs of Timer_A. In addition, it is possible to clock the module by software using the USISWCLK bit when USISSELx = 100.

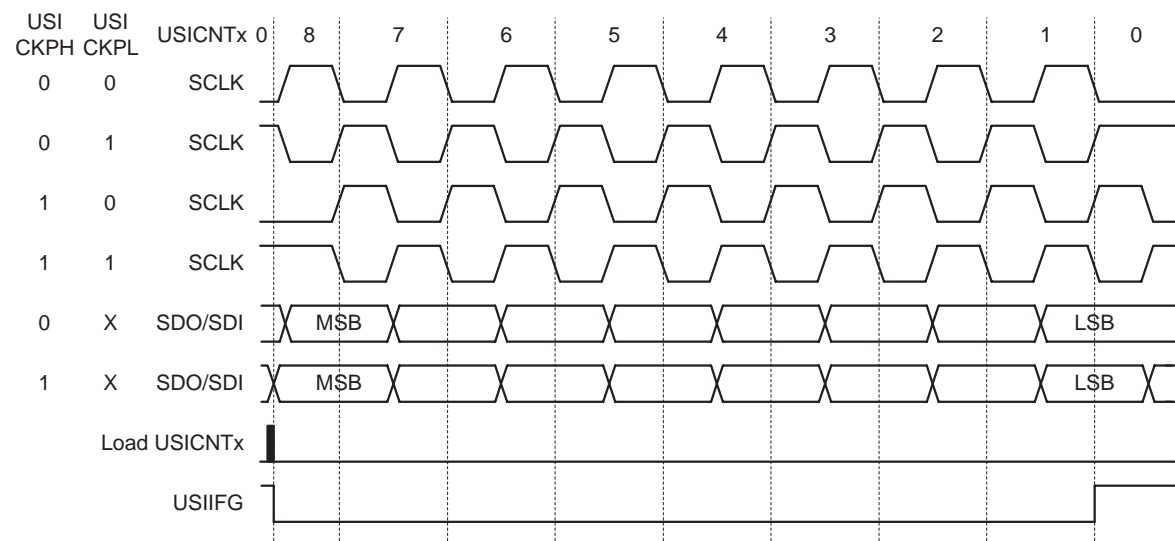

The USIDIVx bits can be used to divide the selected clock by a power of 2 up to 128. The generated clock, USICKLK, is stopped when USIIFG = 1 or when the module operates in slave mode.

The USICKPL bit is used to select the polarity of USICKLK. When USICKPL = 0, the inactive level of USICKLK is low. When USICKPL = 1 the inactive level of USICKLK is high.

11.2.3 SPI Mode

The USI module is configured in SPI mode when USI2C = 0. Control bit USICKPL selects the inactive level of the SPI clock while USICKPH selects the clock edge on which SDO is updated and SDI is sampled. Figure 11–3 shows the clock/data relationship for an 8-bit, MSB-first transfer. USIPE5, USIPE6, and USIPE7 must be set to enable the SCLK, SDO, and SDI port functions.

Figure 11–3. SPI Timing

SPI Master Mode

The USI module is configured as SPI master by setting the master bit USIMST and clearing the I2C bit USI2C. Since the master provides the clock to the slave(s) an appropriate clock source needs to be selected and SCLK configured as output. When USIPE5 = 1, SCLK is automatically configured as an output.

When USIIFG = 0 and USICNTx > 0, clock generation is enabled and the master will begin clocking in/out data using USISR.

Received data must be read from the shift register before new data is written into it for transmission. In a typical application, the USI software will read received data from USISR, write new data to be transmitted to USISR, and enable the module for the next transfer by writing the number of bits to be transferred to USICNTx.

SPI Slave Mode

The USI module is configured as SPI slave by clearing the USIMST and the USI2C bits. In this mode, when USIPE5 = 1 SCLK is automatically configured as an input and the USI receives the clock externally from the master.

If the USI is to transmit data, the shift register must be loaded with the data before the master provides the first clock edge. The output must be enabled by setting USIOE. When USICKPH = 1, the MSB will be visible on SDO immediately after loading the shift register.

The SDO pin can be disabled by clearing the USIOE bit. This is useful if the slave is not addressed in an environment with multiple slaves on the bus.

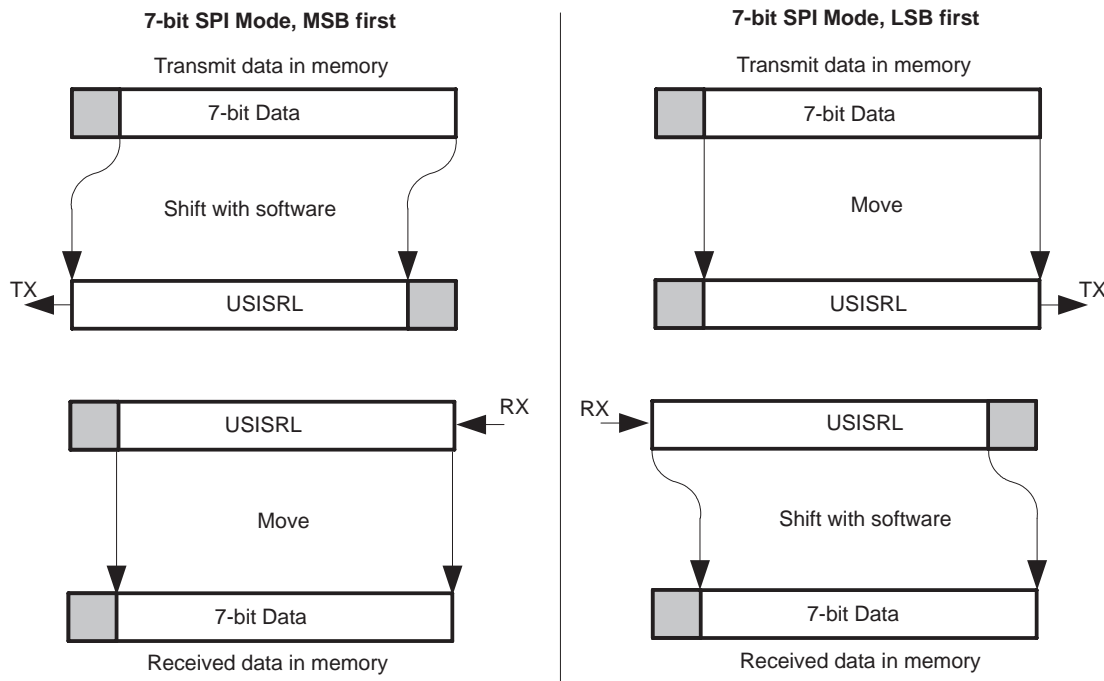

Once all bits are received, the data must be read from USISR and new data loaded into USISR before the next clock edge from the master. In a typical application, after receiving data, the USI software will read the USISR register, write new data to USISR to be transmitted, and enable the USI module for the next transfer by writing the number of bits to be transferred to USICNTx.

USISR Operation

The 16-bit USISR is made up of two 8-bit registers, USISRL and USISRH. Control bit USI16B selects the number of bits of USISR that are used for data transmit and receive. When USI16B = 0, only the lower 8 bits, USISRL, are used.

To transfer < 8 bits, the data must be loaded into USISRL such that unused bits are not shifted out. The data must be MSB- or LSB-aligned depending on USILSB. Figure 11–4 shows an example of 7-bit data handling.

Figure 11–4. Data adjustments for 7-bit SPI Data

When USI16B = 1, all 16 bits are used for data handling. When using USISR to access both USISRL and USISRH, the data needs to be properly adjusted when < 16 bits are used in the same manner as shown in Figure 11–4.

SPI Interrupts

There is one interrupt vector associated with the USI module, and one interrupt flag, USIIFG, relevant for SPI operation. When USIIE and the GIE bit are set, the interrupt flag will generate an interrupt request.

USIIFG is set when USICNTx becomes zero, either by counting or by directly writing 0 to the USICNTx bits. USIIFG is cleared by writing a value > 0 to the USICNTx bits when USIIFGCC = 0, or directly by software.

11.2.4 I²C Mode

The USI module is configured in I²C mode when USI2C = 1, USICKPL = 1, and USICKPH = 0. For I²C data compatibility, USILSB and USI16B must be cleared. USIPE6 and USIPE7 must be set to enable the SCL and SDA port functions.

I²C Master Mode

To configure the USI module as an I²C master the USIMST bit must be set. In master mode, clocks are generated by the USI module and output to the SCL line while USIIFG = 0. When USIIFG = 1, the SCL will stop at the idle, or high, level. Multi-master operation is supported as described in the Arbitration section.

The master supports slaves that are holding the SCL line low only when USIDIVx > 0. When USIDIVx is set to /1 clock division (USIDIVx = 0), connected slaves must not hold the SCL line low during data transmission. Otherwise the communication may fail.

I²C Slave Mode

To configure the USI module as an I²C slave the USIMST bit must be cleared. In slave mode, SCL is held low if USIIFG = 1, USISTTIFG = 1 or if USICNTx = 0. USISTTIFG must be cleared by software after the slave is setup and ready to receive the slave address from a master.

I²C Transmitter

In transmitter mode, data is first loaded into USISRL. The output is enabled by setting USIOE and the transmission is started by writing 8 into USICNTx. This clears USIIFG and SCL is generated in master mode or released from being held low in slave mode. After the transmission of all 8 bits, USIIFG is set, and the clock signal on SCL is stopped in master mode or held low at the next low phase in slave mode.

To receive the I²C acknowledgement bit, the USIOE bit is cleared with software and USICNTx is loaded with 1. This clears USIIFG and one bit is received into USISRL. When USIIFG becomes set again, the LSB of USISRL is the received acknowledge bit and can be tested in software.

```
; Receive ACK/NACK
    BIC.B #USIOE,&USICTL0      ; SDA input
    MOV.B #01h,&USICNT         ; USICNTx = 1
TEST_USIIFG
    BIT.B #USIIFG,&USICTL1     ; Test USIIFG
    JZ     TEST_USIIFG
    BIT.B #01h,&USISRL         ; Test received ACK bit
    JNZ    HANDLE_NACK        ; Handle if NACK
...Else, handle ACK
```

I²C Receiver

In I²C receiver mode the output must be disabled by clearing USIOE and the USI module is prepared for reception by writing 8 into USICNTx. This clears USIIFG and SCL is generated in master mode or released from being held low in slave mode. The USIIFG bit will be set after 8 clocks. This stops the clock signal on SCL in master mode or holds SCL low at the next low phase in slave mode.

To transmit an acknowledge or no-acknowledge bit, the MSB of the shift register is loaded with 0 or 1, the USIOE bit is set with software to enable the output, and 1 is written to the USICNTx bits. As soon as the MSB bit is shifted out, USIIFG will be become set and the module can be prepared for the reception of the next I²C data byte.

```
; Generate ACK
    BIS.B  #USIOE,&USICTL0      ; SDA output
    MOV.B  #00h,&USISRL         ; MSB = 0
    MOV.B  #01h,&USICNT         ; USICNTx = 1
TEST_USIIFG
    BIT.B  #USIIFG,&USICTL1     ; Test USIIFG
    JZ     TEST_USIIFG
...continue...

; Generate NACK
    BIS.B  #USIOE,&USICTL0      ; SDA output
    MOV.B  #0FFh,&USISRL        ; MSB = 1
    MOV.B  #01h,&USICNT         ; USICNTx = 1
TEST_USIIFG
    BIT.B  #USIIFG,&USICTL1     ; Test USIIFG
    JZ     TEST_USIIFG
...continue...
```

START Condition

A START condition is a high-to-low transition on SDA while SCL is high. The START condition can be generated by setting the MSB of the shift register to 0. Setting the USIGE and USIOE bits makes the output latch transparent and the MSB of the shift register is immediately presented to SDA and pulls the line low. Clearing USIGE resumes the clocked-latch function and holds the 0 on SDA until data is shifted out with SCL.

```
; Generate START
    MOV.B  #000h,&USISRL        ; MSB = 0
    BIS.B  #USIGE+USIOE,&USICTL0 ; Latch/SDA output enabled
    BIC.B  #USIGE,&USICTL0       ; Latch disabled
...continue...
```

STOP Condition

A STOP condition is a low-to-high transition on SDA while SCL is high. To finish the acknowledgment bit and pull SDA low to prepare the STOP condition generation requires clearing the MSB in the shift register and loading 1 into USICNTx. This will generate a low pulse on SCL and during the low phase SDA is pulled low. SCL stops in the idle, or high, state since the module is in master mode. To generate the low-to-high transition, the MSB is set in the shift register and USICNTx is loaded with 1. Setting the USIGE and USIOE bits makes the output latch transparent and the MSB of USISRL releases SDA to the idle state. Clearing USIGE stores the MSB in the output latch and the output is disabled by clearing USIOE. SDA remains high until a START condition is generated because of the external pull-up..

```
; Generate STOP
    BIS.B  #USIOE,&USICTL0 ; SDA=output
    MOV.B  #000H,&USISRL   ; MSB = 0
    MOV.B  #001H,&USICNT   ; USICNT = 1 for one clock
TEST_USIIFG
    BIT.B  #USIIFG,&USICTL1 ; Test USIIFG
    JZ TEST_USIIFG          ;
    MOV.B  #0FFH,&USISRL   ; USISRL = 1 to drive SDA high
    BIS.B  #USIGE,&USICTL0 ; Transparent latch enabled
    BIC.B  #USIGE+USIOE,&USICTL; Latch/SDA output disabled
...continue...
```

Releasing SCL

Setting the USISCLREL bit will release SCL if it is being held low by the USI module without requiring USIIFG to be cleared. The USISCLREL bit will be cleared automatically if a START condition is received and the SCL line will be held low on the next clock.

In slave operation this bit should be used to prevent SCL from being held low when the slave has detected that it was not addressed by the master. On the next START condition USISCLREL will be cleared and the USISTTIFG will be set.

Arbitration

The USI module can detect a lost arbitration condition in multi-master I²C systems. The I²C arbitration procedure uses the data presented on SDA by the competing transmitters. The first master transmitter that generates a logic high loses arbitration to the opposing master generating a logic low. The loss of arbitration is detected in the USI module by comparing the value presented to the bus and the value read from the bus. If the values are not equal arbitration is lost and the arbitration lost flag, USIAL, is set. This also clears the output enable bit USIOE and the USI module no longer drives the bus. In this case, user software must check the USIAL flag together with USIIFG and configure the USI to slave receiver when arbitration is lost. The USIAL flag must be cleared by software.

To prevent other faster masters from generating clocks during the arbitration procedure SCL is held low if another master on the bus drives SCL low and USIIFG or USISTTIFG is set, or if USICNTx = 0.

I²C Interrupts

There is one interrupt vector associated with the USI module with two interrupt flags relevant for I²C operation, USIIFG and USISTTIFG. Each interrupt flag has its own interrupt enable bit, USIIE and USISTTIE. When an interrupt is enabled, and the GIE bit is set, a set interrupt flag will generate an interrupt request.

USIIFG is set when USICNTx becomes zero, either by counting or by directly writing 0 to the USICNTx bits. USIIFG is cleared by writing a value > 0 to the USICNTx bits when USIIFGCC = 0, or directly by software.

USISTTIFG is set when a START condition is detected. The USISTTIFG flag must be cleared by software.

The reception of a STOP condition is indicated with the USISTP flag but there is no interrupt function associated with the USISTP flag. USISTP is cleared by writing a value > 0 to the USICNTx bits when USIIFGCC = 0 or directly by software.

11.3 USI Registers

The USI registers are listed in Table 11–1:

Table 11–1. USI Registers

Register	Short Form	Register Type	Address	Initial State
USI control register 0	USICTL0	Read/write	078h	01h with PUC
USI control register 1	USICTL1	Read/write	079h	01h with PUC
USI clock control	USICKCTL	Read/write	07Ah	Reset with PUC
USI bit counter	USICNT	Read/write	07Bh	Reset with PUC
USI low byte shift register	USISRL	Read/write	07Ch	Unchanged
USI high byte shift register	USISRH	Read/write	07Dh	Unchanged

The USI registers can be accessed with word instructions as shown in Table 11–2:

Table 11–2. Word Access to USI Registers

Register	Short Form	High-Byte Register	Low-Byte Register	Address
USI control register	USICTL	USICTL1	USICTL0	078h
USI clock and counter control register	USICCTL	USICNT	USICKCTL	07Ah
USI shift register	USISR	USISRH	USISRL	07Ch

USICTL0, USI Control Register 0

Universal Serial Communication Interface, UART Mode

The universal serial communication interface (USCI) supports multiple serial communication modes with one hardware module. This chapter discusses the operation of the asynchronous UART mode.

Topic	Page
12.1 USCI Overview	12-2
12.2 USCI Introduction: UART Mode	12-3
12.3 USCI Operation: UART Mode	12-5
12.4 USCI Registers: UART Mode	12-28

12.1 USCI Overview

The universal serial communication interface (USCI) modules support multiple serial communication modes. Different USCI modules support different modes. Each different USCI module is named with a different letter. For example, USCI_A is different from USCI_B, etc. If more than one identical USCI module is implemented on one device, those modules are named with incrementing numbers. For example, if one device has two USCI_A modules, they are named USCI_A0 and USCI_A1. See the device-specific datasheet to determine which USCI modules, if any, are implemented on which devices.

The USCI_Ax modules support:

- ☐ UART mode
- ☐ Pulse shaping for IrDA communications
- ☐ Automatic baud rate detection for LIN communications
- ☐ SPI mode

The USCI_Bx modules support:

- ☐ I²C mode
- ☐ SPI mode

12.2 USCI Introduction: UART Mode

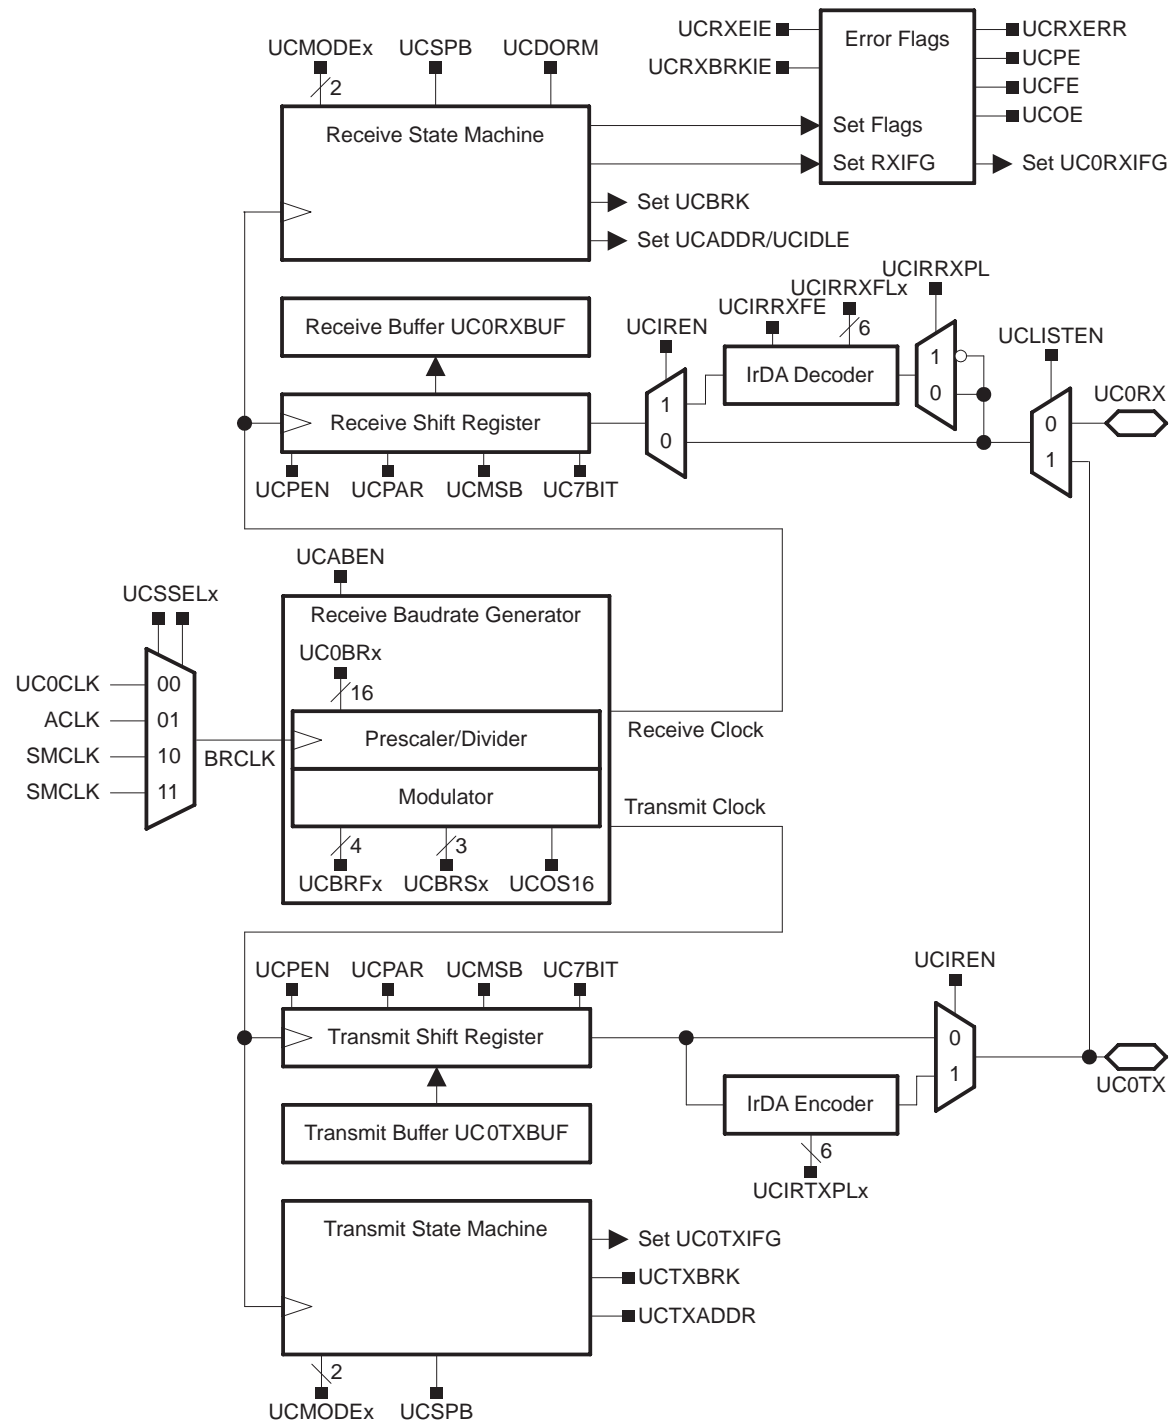

In asynchronous mode, the USCI_Ax modules connect the MSP430 to an external system via two external pins, UCAxRXD and UCAxTXD. UART mode is selected when the UCSYNC bit is cleared.

UART mode features include:

- ☐ 7- or 8-bit data with odd, even, or non-parity
- ☐ Independent transmit and receive shift registers
- ☐ Separate transmit and receive buffer registers
- ☐ LSB-first or MSB-first data transmit and receive
- ☐ Built-in idle-line and address-bit communication protocols for multiprocessor systems
- ☐ Receiver start-edge detection for auto-wake up from LPMx modes
- ☐ Programmable baud rate with modulation for fractional baud rate support
- ☐ Status flags for error detection and suppression
- ☐ Status flags for address detection
- ☐ Independent interrupt capability for receive and transmit

Figure 12–1 shows the USCI_Ax when configured for UART mode.

Figure 12–1. USCI_Ax Block Diagram: UART Mode (UCSYNC = 0)

12.3 USCI Operation: UART Mode

In UART mode, the USCI transmits and receives characters at a bit rate asynchronous to another device. Timing for each character is based on the selected baud rate of the USCI. The transmit and receive functions use the same baud rate frequency.

12.3.1 USCI Initialization and Reset

The USCI is reset by a PUC or by setting the UCSWRST bit. After a PUC, the UCSWRST bit is automatically set, keeping the USCI in a reset condition. When set, the UCSWRST bit resets the UCAxRXIE, UCAxTXIE, UCAxRXIFG, UCRXERR, UCBRK, UCPE, UCOE, UCFE, UCSTOE and UCBTOE bits and sets the UCAxTXIFG bit. Clearing UCSWRST releases the USCI for operation.

Note: Initializing or Re-Configuring the USCI Module

The recommended USCI initialization/re-configuration process is:

- 1) Set UCSWRST (`BIS.B #UCSWRST, &UCAxCTL1`)
- 2) Initialize all USCI registers with UCSWRST = 1 (including UCAxCTL1)
- 3) Configure ports.
- 4) Clear UCSWRST via software (`BIC.B #UCSWRST, &UCAxCTL1`)
- 5) Enable interrupts (optional) via UCAxRXIE and/or UCAxTXIE

12.3.2 Character Format

The UART character format, shown in Figure 12–2, consists of a start bit, seven or eight data bits, an even/odd/no parity bit, an address bit (address-bit mode), and one or two stop bits. The UCMSB bit controls the direction of the transfer and selects LSB or MSB first. LSB-first is typically required for UART communication.

Figure 12–2. Character Format

12.3.3 Asynchronous Communication Formats

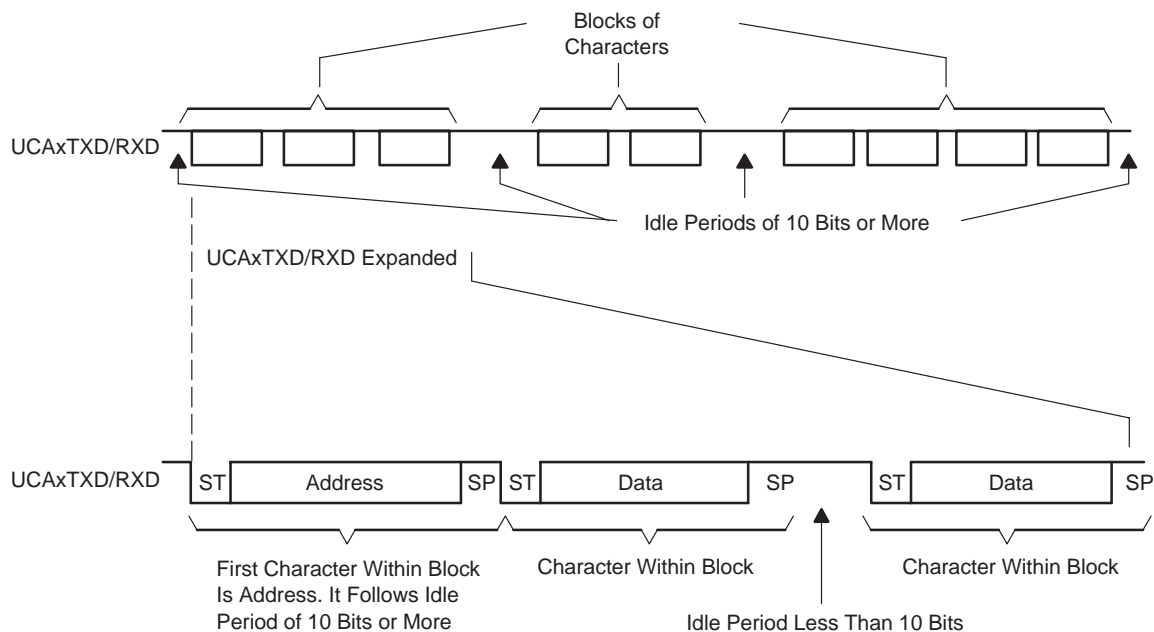

When two devices communicate asynchronously, no multiprocessor format is required for the protocol. When three or more devices communicate, the USCI supports the idle-line and address-bit multiprocessor communication formats.

Idle-Line Multiprocessor Format

When $UCMODEx = 01$, the idle-line multiprocessor format is selected. Blocks of data are separated by an idle time on the transmit or receive lines as shown in Figure 12–3. An idle receive line is detected when 10 or more continuous ones (marks) are received after the one or two stop bits of a character. The baud rate generator is switched off after reception of an idle line until the next start edge is detected. When an idle line is detected the UCIDLE bit is set.

The first character received after an idle period is an address character. The UCIDLE bit is used as an address tag for each block of characters. In idle-line multiprocessor format, this bit is set when a received character is an address

Figure 12–3. Idle-Line Format

The UCDORM bit is used to control data reception in the idle-line multiprocessor format. When UCDORM = 1, all non-address characters are assembled but not transferred into the UCAxRXBUF, and interrupts are not generated. When an address character is received, the character is transferred into UCAxRXBUF, UCAxRXIFG is set, and any applicable error flag is set when UCRXEIE = 1. When UCRXEIE = 0 and an address character is received but has a framing error or parity error, the character is not transferred into UCAxRXBUF and UCAxRXIFG is not set.

If an address is received, user software can validate the address and must reset UCDORM to continue receiving data. If UCDORM remains set, only address characters will be received. When UCDORM is cleared during the reception of a character the receive interrupt flag will be set after the reception completed. The UCDORM bit is not modified by the USCI hardware automatically.

For address transmission in idle-line multiprocessor format, a precise idle period can be generated by the USCI to generate address character identifiers on UCAxTXD. The double-buffered UCTXADDR flag indicates if the next character loaded into UCAxTXBUF is preceded by an idle line of 11 bits. UCTXADDR is automatically cleared when the start bit is generated.

Transmitting an Idle Frame

The following procedure sends out an idle frame to indicate an address character followed by associated data:

- 1) Set UCTXADDR, then write the address character to UCAxTXBUF. UCAxTXBUF must be ready for new data (UCAxTXIFG = 1).

This generates an idle period of exactly 11 bits followed by the address character. UCTXADDR is reset automatically when the address character is transferred from UCAxTXBUF into the shift register.

- 2) Write desired data characters to UCAxTXBUF. UCAxTXBUF must be ready for new data (UCAxTXIFG = 1).

The data written to UCAxTXBUF is transferred to the shift register and transmitted as soon as the shift register is ready for new data.

The idle-line time must not be exceeded between address and data transmission or between data transmissions. Otherwise, the transmitted data will be misinterpreted as an address.

Address-Bit Multiprocessor Format

When UCMODEx = 10, the address-bit multiprocessor format is selected. Each processed character contains an extra bit used as an address indicator shown in Figure 12–4. The first character in a block of characters carries a set address bit which indicates that the character is an address. The USCI UCADDR bit is set when a received character has its address bit set and is transferred to UCAxRXBUF.

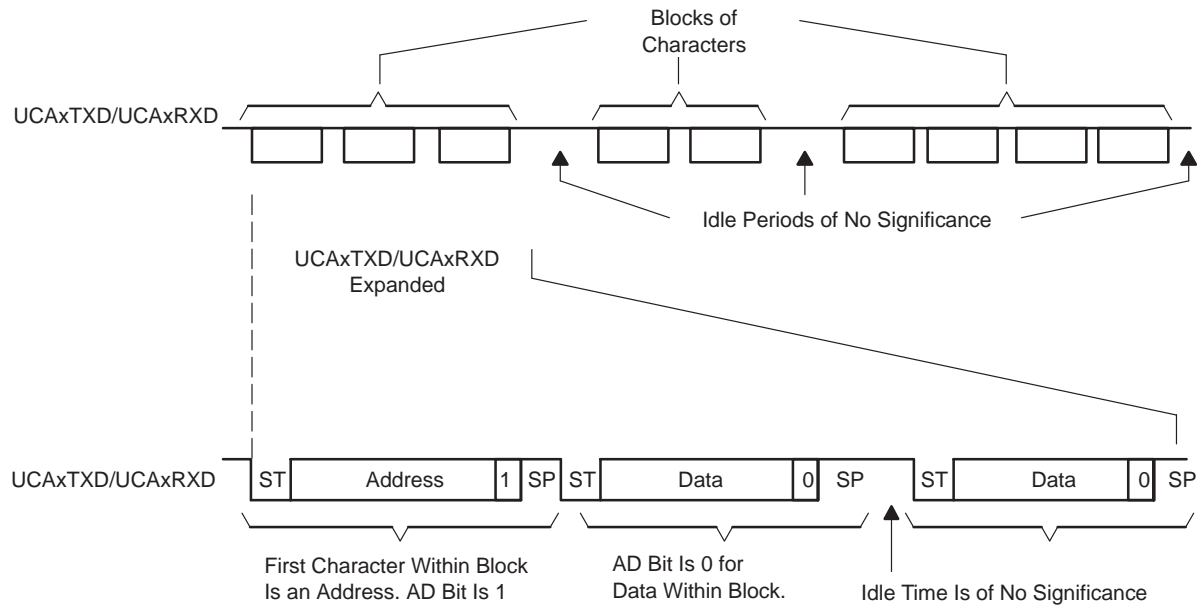

The UCDORM bit is used to control data reception in the address-bit multiprocessor format. When UCDORM is set, data characters with address bit = 0 are assembled by the receiver but are not transferred to UCAxRXBUF and no interrupts are generated. When a character containing a set address bit is received, the character is transferred into UCAxRXBUF, UCAxRXIFG is set, and any applicable error flag is set when UCRXEIE = 1. When UCRXEIE = 0 and a character containing a set address bit is received, but has a framing error or parity error, the character is not transferred into UCAxRXBUF and UCAxRXIFG is not set.

If an address is received, user software can validate the address and must reset UCDORM to continue receiving data. If UCDORM remains set, only address characters with address bit = 1 will be received. The UCDORM bit is not modified by the USCI hardware automatically.

When UCDORM = 0 all received characters will set the receive interrupt flag UCAxRXIFG. If UCDORM is cleared during the reception of a character the receive interrupt flag will be set after the reception is completed.

For address transmission in address-bit multiprocessor mode, the address bit of a character is controlled by the UCTXADDR bit. The value of the UCTXADDR bit is loaded into the address bit of the character transferred from UCAxTXBUF to the transmit shift register. UCTXADDR is automatically cleared when the start bit is generated.

Figure 12–4. Address-Bit Multiprocessor Format

Break Reception and Generation

When $UCMODEx = 00, 01, \text{ or } 10$ the receiver detects a break when all data, parity, and stop bits are low, regardless of the parity, address mode, or other character settings. When a break is detected, the $UCBRK$ bit is set. If the break interrupt enable bit, $UCBRKIE$, is set, the receive interrupt flag $UCAxRXIFG$ will also be set. In this case, the value in $UCAxRXBUF$ is $0h$ since all data bits were zero.

To transmit a break set the $UCTXBRK$ bit, then write $0h$ to $UCAxTXBUF$. $UCAxTXBUF$ must be ready for new data ($UCAxTXIFG = 1$). This generates a break with all bits low. $UCTXBRK$ is automatically cleared when the start bit is generated.

12.3.4 Automatic Baud Rate Detection

When $UCMODEx = 11$ UART mode with automatic baud rate detection is selected. For automatic baud rate detection, a data frame is preceded by a synchronization sequence that consists of a break and a synch field. A break is detected when 11 or more continuous zeros (spaces) are received. If the length of the break exceeds 22 bit times the break timeout error flag $UCBTOE$ is set. The synch field follows the break as shown in Figure 12–5.

Figure 12–5. Auto Baud Rate Detection – Break/Synch Sequence

For LIN conformance the character format should be set to 8 data bits, LSB first, no parity and one stop bit. No address bit is available.

The synch field consists of the data 055h inside a byte field as shown in Figure 12–6. The synchronization is based on the time measurement between the first falling edge and the last falling edge of the pattern. The transmit baud rate generator is used for the measurement if automatic baud rate detection is enabled by setting $UCABDEN$. Otherwise, the pattern is received but not measured. The result of the measurement is transferred into the baud rate control registers $UCAxBR0$, $UCAxBR1$, and $UCAxMCTL$. If the length of the synch field exceeds the measurable time the synch timeout error flag $UCSTOE$ is set.

Figure 12–6. Auto Baud Rate Detection – Synch Field

The $UCDORM$ bit is used to control data reception in this mode. When $UCDORM$ is set, all characters are received but not transferred into the $UCAxRXBUF$, and interrupts are not generated. When a break/synch field is detected the $UCBRK$ flag is set. The character following the break/synch field is transferred into $UCAxRXBUF$ and the $UCAxRXIFG$ interrupt flag is set. Any applicable error flag is also set. If the $UCBRKIE$ bit is set, reception of the break/synch sets the $UCAxRXIFG$. The $UCBRK$ bit is reset by user software or by reading the receive buffer $UCAxRXBUF$.

When a break/synch field is received, user software must reset UCDORM to continue receiving data. If UCDORM remains set, only the character after the next reception of a break/synch field will be received. The UCDORM bit is not modified by the USCI hardware automatically.

When UCDORM = 0 all received characters will set the receive interrupt flag UCAxRXIFG. If UCDORM is cleared during the reception of a character the receive interrupt flag will be set after the reception is complete.

Transmitting a Break/Synch Field

The following procedure transmits a break/synch field:

- 1) Set UCTXBRK with UMODEx = 11.
- 2) Write 055h to UCAxTXBUF. UCAxTXBUF must be ready for new data (UCAxTXIFG = 1).

This generates a break field of 13 bits followed by a break delimiter and the synch character. The length of the break delimiter is controlled with the UCDELIMx bits. UCTXBRK is reset automatically when the synch character is transferred from UCAxTXBUF into the shift register.

- 3) Write desired data characters to UCAxTXBUF. UCAxTXBUF must be ready for new data (UCAxTXIFG = 1).

The data written to UCAxTXBUF is transferred to the shift register and transmitted as soon as the shift register is ready for new data.

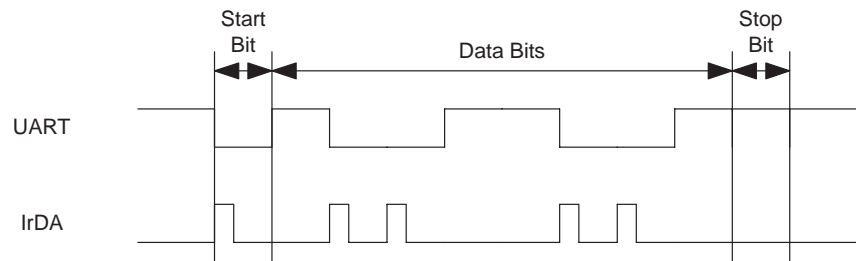

12.3.5 IrDA Encoding and Decoding

When UCIREN is set the IrDA encoder and decoder are enabled and provide hardware bit shaping for IrDA communication.

IrDA Encoding

The encoder sends a pulse for every zero bit in the transmit bit stream coming from the UART as shown in Figure 12–7. The pulse duration is defined by UCIRTXPLx bits specifying the number of half clock periods of the clock selected by UCIRTXCLK.

Figure 12–7. UART vs. IrDA Data Format

To set the pulse time of 3/16 bit period required by the IrDA standard the BITCLK16 clock is selected with UCIRTXCLK = 1 and the pulse length is set to 6 half clock cycles with UCIRTXPLx = 6 – 1 = 5.

When UCIRTXCLK = 0, the pulse length t_{PULSE} is based on BRCLK and is calculated as follows:

$$UCIRTXPLx = t_{PULSE} \cdot 2 \cdot f_{BRCLK} - 1$$

When UCIRTXCLK = 0 the prescaler UCBRx must to be set to a value greater or equal to 5.

IrDA Decoding

The decoder detects high pulses when UCIRRXPL = 0. Otherwise it detects low pulses. In addition to the analog deglitch filter an additional programmable digital filter stage can be enabled by setting UCIRRXFE. When UCIRRXFE is set, only pulses longer than the programmed filter length are passed. Shorter pulses are discarded. The equation to program the filter length UCIRRXFLx is:

$$UCIRRXFLx = (t_{PULSE} - t_{WAKE}) \cdot 2 \cdot f_{BRCLK} - 4$$

where:

- t_{PULSE} : Minimum receive pulse width
- t_{WAKE} : Wake time from any low power mode. Zero when MSP430 is in active mode.

12.3.6 Automatic Error Detection

Glitch suppression prevents the USCI from being accidentally started. Any pulse on UCAXRXD shorter than the deglitch time t_{τ} (approximately 150 ns) will be ignored. See the device-specific datasheet for parameters.

When a low period on UCAXRXD exceeds t_{τ} a majority vote is taken for the start bit. If the majority vote fails to detect a valid start bit the USCI halts character reception and waits for the next low period on UCAXRXD. The majority vote is also used for each bit in a character to prevent bit errors.

The USCI module automatically detects framing errors, parity errors, overrun errors, and break conditions when receiving characters. The bits UCFE, UCPE, UCOE, and UCBRK are set when their respective condition is detected. When the error flags UCFE, UCPE or UCOE are set, UCRXERR is also set. The error conditions are described in Table 12–1.

Table 12–1. Receive Error Conditions

Error Condition	Error Flag	Description
Framing error	UCFE	A framing error occurs when a low stop bit is detected. When two stop bits are used, both stop bits are checked for framing error. When a framing error is detected, the UCFE bit is set.
Parity error	UCPE	A parity error is a mismatch between the number of 1s in a character and the value of the parity bit. When an address bit is included in the character, it is included in the parity calculation. When a parity error is detected, the UCPE bit is set.
Receive overrun	UCOE	An overrun error occurs when a character is loaded into UCAXRXBUF before the prior character has been read. When an overrun occurs, the UCOE bit is set.
Break condition	UCBRK	When not using automatic baud rate detection, a break is detected when all data, parity, and stop bits are low. When a break condition is detected, the UCBRK bit is set. A break condition can also set the interrupt flag UCAXRXIFG if the break interrupt enable UCBRKIE bit is set.

When UCRXEIE = 0 and a framing error, or parity error is detected, no character is received into UCAXRXBUF. When UCRXEIE = 1, characters are received into UCAXRXBUF and any applicable error bit is set.

When UCFE, UCPE, UCOE, UCBRK, or UCRXERR is set, the bit remains set until user software resets it or UCAXRXBUF is read. UCOE must be reset by reading UCAXRXBUF. Otherwise it will not function properly.

12.3.7 USCI Receive Enable

The USCI module is enabled by clearing the UCSWRST bit and the receiver is ready and in an idle state. The receive baud rate generator is in a ready state but is not clocked nor producing any clocks.

The falling edge of the start bit enables the baud rate generator and the UART state machine checks for a valid start bit. If no valid start bit is detected the UART state machine returns to its idle state and the baud rate generator is turned off again. If a valid start bit is detected a character will be received.

When the idle-line multiprocessor mode is selected with UCMODEx = 01 the UART state machine checks for an idle line after receiving a character. If a start bit is detected another character is received. Otherwise the UCIDLE flag is set after 10 ones are received and the UART state machine returns to its idle state and the baud rate generator is turned off.

Receive Data Glitch Suppression

Glitch suppression prevents the USCI from being accidentally started. Any glitch on UCAXRXD shorter than the deglitch time t_{τ} (approximately 150 ns) will be ignored by the USCI and further action will be initiated as shown in Figure 12–8. See the device-specific datasheet for parameters.

Figure 12–8. Glitch Suppression, USCI Receive Not Started

When a glitch is longer than t_{τ} , or a valid start bit occurs on UCAXRXD, the USCI receive operation is started and a majority vote is taken as shown in Figure 12–9. If the majority vote fails to detect a start bit the USCI halts character reception.

Figure 12–9. Glitch Suppression, USCI Activated

12.3.8 USCI Transmit Enable

The USCI module is enabled by clearing the UCSWRST bit and the transmitter is ready and in an idle state. The transmit baud rate generator is ready but is not clocked nor producing any clocks.

A transmission is initiated by writing data to UCAtXBUF. When this occurs, the baud rate generator is enabled and the data in UCAtXBUF is moved to the transmit shift register on the next BITCLK after the transmit shift register is empty. UCAtXIFG is set when new data can be written into UCAtXBUF.

Transmission continues as long as new data is available in UCAtXBUF at the end of the previous byte transmission. If new data is not in UCAtXBUF when the previous byte has transmitted, the transmitter returns to its idle state and the baud rate generator is turned off.

12.3.9 UART Baud Rate Generation

The USCI baud rate generator is capable of producing standard baud rates from non-standard source frequencies. It provides two modes of operation selected by the UCOS16 bit.

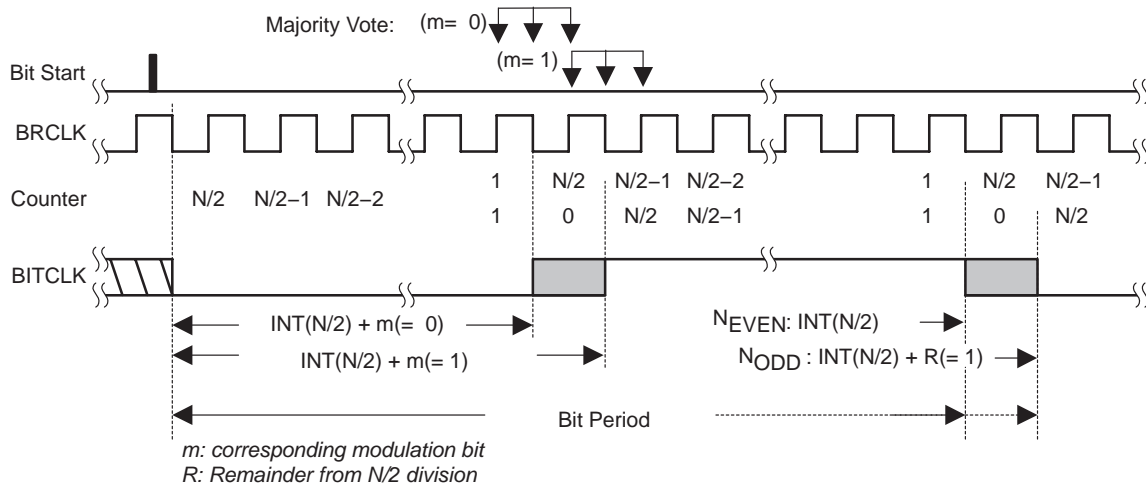

Low-Frequency Baud Rate Generation

The low-frequency mode is selected when UCOS16 = 0. This mode allows generation of baud rates from low frequency clock sources (e.g. 9600 baud from a 32768Hz crystal). By using a lower input frequency the power consumption of the module is reduced. Using this mode with higher frequencies and higher prescaler settings will cause the majority votes to be taken in an increasingly smaller window and thus decrease the benefit of the majority vote.

In low-frequency mode the baud rate generator uses one prescaler and one modulator to generate bit clock timing. This combination supports fractional divisors for baud rate generation. In this mode, the maximum USCI baud rate is one-third the UART source clock frequency BRCLK.

Timing for each bit is shown in Figure 12–10. For each bit received, a majority vote is taken to determine the bit value. These samples occur at the $N/2 - 1/2$, $N/2$, and $N/2 + 1/2$ BRCLK periods, where N is the number of BRCLKs per BITCLK.

Figure 12–10. BITCLK Baud Rate Timing with UCOS16 = 0

Modulation is based on the UCBRSx setting as shown in Table 12–2. A 1 in the table indicates that $m = 1$ and the corresponding BITCLK period is one BRCLK period longer than a BITCLK period with $m = 0$. The modulation wraps around after 8 bits but restarts with each new start bit.

Table 12–2. BITCLK Modulation Pattern

UCBRSx	Bit 0 (Start Bit)	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7
0	0	0	0	0	0	0	0	0
1	0	1	0	0	0	0	0	0
2	0	1	0	0	0	1	0	0
3	0	1	0	1	0	1	0	0
4	0	1	0	1	0	1	0	1
5	0	1	1	1	0	1	0	1
6	0	1	1	1	0	1	1	1
7	0	1	1	1	1	1	1	1

Oversampling Baud Rate Generation

The oversampling mode is selected when UCOS16 = 1. This mode supports sampling a UART bit stream with higher input clock frequencies. This results in majority votes that are always 1/16 of a bit clock period apart. This mode also easily supports IrDA pulses with a 3/16 bit-time when the IrDA encoder and decoder are enabled.

This mode uses one prescaler and one modulator to generate the BITCLK16 clock that is 16 times faster than the BITCLK. An additional divider and modulator stage generates BITCLK from BITCLK16. This combination supports fractional divisions of both BITCLK16 and BITCLK for baud rate generation. In this mode, the maximum USCI baud rate is 1/16 the UART source clock frequency BRCLK. When UCBRx is set to 0 or 1 the first prescaler and modulator stage is bypassed and BRCLK is equal to BITCLK16.

Modulation for BITCLK16 is based on the UCBRFx setting as shown in Table 12–3. A 1 in the table indicates that the corresponding BITCLK16 period is one BRCLK period longer than the periods m=0. The modulation restarts with each new bit timing.

Modulation for BITCLK is based on the UCBSRx setting as shown in Table 12–2 as previously described.

Table 12–3. BITCLK16 Modulation Pattern

UCBRFx	No. of BITCLK16 Clocks after last falling BITCLK edge															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
00h	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

12.3.10 Setting a Baud Rate

For a given BRCLK clock source, the baud rate used determines the required division factor N:

$$N = \frac{f_{\text{BRCLK}}}{\text{Baudrate}}$$

The division factor N is often a non-integer value thus at least one divider and one modulator stage is used to meet the factor as closely as possible.

If N is equal or greater than 16 the oversampling baud rate generation mode can be chosen by setting UCOS16.

Low-Frequency Baud Rate Mode Setting

In the low-frequency mode, the integer portion of the divisor is realized by the prescaler:

$$\text{UCBRx} = \text{INT}(N)$$

and the fractional portion is realized by the modulator with the following nominal formula:

$$\text{UCBRSx} = \text{round}((N - \text{INT}(N)) * 8)$$

Incrementing or decrementing the UCBRSx setting by one count may give a lower maximum bit error for any given bit. To determine if this is the case, a detailed error calculation must be performed for each bit for each UCBRSx setting.

Oversampling Baud Rate Mode Setting

In the oversampling mode the prescaler is set to:

$$\text{UCBRx} = \text{INT}(N/16).$$

and the first stage modulator is set to:

$$\text{UCBRFx} = \text{round}((N/16 - \text{INT}(N/16)) * 16)$$

When greater accuracy is required, the UCBRSx modulator can also be implemented with values from 0 – 7. To find the setting that gives the lowest maximum bit error rate for any given bit, a detailed error calculation must be performed for all settings of UCBRSx from 0 – 7 with the initial UCBRFx setting and with the UCBRFx setting incremented and decremented by one.

12.3.11 Transmit Bit Timing

The timing for each character is the sum of the individual bit timings. Using the modulation features of the baud rate generator reduces the cumulative bit error. The individual bit error can be calculated using the following steps.

Low-Frequency Baud Rate Mode Bit Timing

In low-frequency mode, calculate the length of bit i $T_{\text{bit,TX}}[i]$ based on the UCBRx and UCBRSx settings:

$$T_{\text{bit,TX}}[i] = \frac{1}{f_{\text{BRCLK}}} (\text{UCBRx} + m_{\text{UCBRSx}}[i])$$

where:

$m_{\text{UCBRSx}}[i]$: Modulation of bit i from Table 12–2

Oversampling Baud Rate Mode Bit Timing

In oversampling baud rate mode calculate the length of bit i $T_{\text{bit,TX}}[i]$ based on the baud rate generator UCBRx, UCBRFx and UCBRSx settings:

$$T_{\text{bit,TX}}[i] = \frac{1}{f_{\text{BRCLK}}} \left((16 + m_{\text{UCBRSx}}[i]) \cdot \text{UCBRx} + \sum_{j=0}^{15} m_{\text{UCBRFx}}[j] \right)$$

where:

$\sum_{j=0}^{15} m_{\text{UCBRFx}}[j]$: Sum of ones from the corresponding row in Table 12–3

$m_{\text{UCBRSx}}[i]$: Modulation of bit i from Table 12–2

This results in an end-of-bit time $t_{\text{bit,TX}}[i]$ equal to the sum of all previous and the current bit times:

$$t_{\text{bit,TX}}[i] = \sum_{j=0}^i T_{\text{bit,TX}}[j]$$

To calculate bit error, this time is compared to the ideal bit time $t_{\text{bit,ideal,TX}}[i]$:

$$t_{\text{bit,ideal,TX}}[i] = \frac{1}{\text{Baudrate}} (i + 1)$$

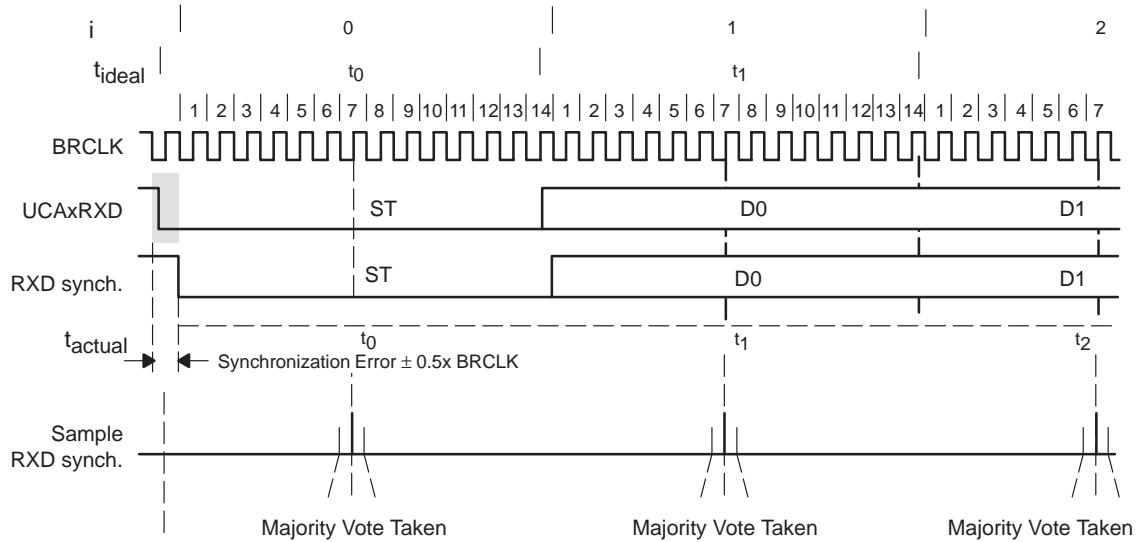

This results in an error normalized to one ideal bit time (1/baudrate):

$$\text{Error}_{\text{TX}}[i] = (t_{\text{bit,TX}}[i] - t_{\text{bit,ideal,TX}}[i]) \cdot \text{Baudrate} \cdot 100\%$$

12.3.12 Receive Bit Timing

Receive timing error consists of two error sources. The first is the bit-to-bit timing error similar to the transmit bit timing error. The second is the error between a start edge occurring and the start edge being accepted by the USCI module. Figure 12–11 shows the asynchronous timing errors between data on the UCAxRXD pin and the internal baud-rate clock. This results in an additional synchronization error. The synchronization error t_{SYNC} is between -0.5 BRCLKs and $+0.5 \text{ BRCLKs}$ independent of the selected baud rate generation mode.

Figure 12–11. Receive Error

The ideal sampling time $t_{\text{bit,ideal,RX}}[i]$ is in the middle of a bit period:

$$t_{\text{bit,ideal,RX}}[i] = \frac{1}{\text{Baudrate}}(i + 0.5)$$

The real sampling time $t_{\text{bit,RX}}[i]$ is equal to the sum of all previous bits according to the formulas shown in the transmit timing section, plus one half BITCLK for the current bit i , plus the synchronization error t_{SYNC} .

This results in the following $t_{\text{bit,RX}}[i]$ for the low-frequency baud rate mode

$$t_{\text{bit,RX}}[i] = t_{\text{SYNC}} + \sum_{j=0}^{i-1} T_{\text{bit,RX}}[j] + \frac{1}{f_{\text{BRCLK}}} \left(\text{INT}\left(\frac{1}{2} \text{UCBRx}\right) + m_{\text{UCBRsx}}[i] \right)$$

where:

$$T_{\text{bit,RX}}[i] = \frac{1}{f_{\text{BRCLK}}} (\text{UCBRx} + m_{\text{UCBRsx}}[i])$$

$m_{\text{UCBRsx}}[i]$: Modulation of bit i from Table 12–2

For the oversampling baud rate mode the sampling time $t_{\text{bit,RX}}[i]$ of bit i is calculated by:

$$t_{\text{bit,RX}}[i] = t_{\text{SYNC}} + \sum_{j=0}^{i-1} T_{\text{bit,RX}}[j] + \frac{1}{f_{\text{BRCLK}}} \left((8 + m_{\text{UCBRSx}}[i]) \cdot \text{UCBRx} + \sum_{j=0}^{7+m_{\text{UCBRSx}}[i]} m_{\text{UCBRFx}}[j] \right)$$

where:

$$T_{\text{bit,RX}}[i] = \frac{1}{f_{\text{BRCLK}}} \left((16 + m_{\text{UCBRSx}}[i]) \cdot \text{UCBRx} + \sum_{j=0}^{15} m_{\text{UCBRFx}}[j] \right)$$

$\sum_{j=0}^{7+m_{\text{UCBRSx}}[i]} m_{\text{UCBRFx}}[j]$: Sum of ones from columns 0 – 7 + $m_{\text{UCBRSx}}[i]$ from the corresponding row in Table 12–3

$m_{\text{UCBRSx}}[i]$: Modulation of bit i from Table 12–2

This results in an error normalized to one ideal bit time (1/baudrate) according to the following formula:

$$\text{Error}_{\text{RX}}[i] = (t_{\text{bit,RX}}[i] - t_{\text{bit,ideal,RX}}[i]) \cdot \text{Baudrate} \cdot 100\%$$

12.3.13 Typical Baud Rates and Errors

Standard baud rate data for UCBRx, UCBRSx and UCBRFx are listed in Table 12–4 and Table 12–5 for a 32,768 Hz crystal sourcing ACLK and typical SMCLK frequencies.

The receive error is the accumulated time versus the ideal scanning time in the middle of each bit. The worst case error is given for the reception of an 8-bit character with parity and one stop bit including synchronization error.

The transmit error is the accumulated timing error versus the ideal time of the bit period. The worst case error is given for the transmission of an 8-bit character with parity and stop bit.

Table 12–4. Commonly Used Baud Rates, Settings, and Errors, UCOS16 = 0

12.3.14 Using the USCI Module in UART Mode with Low Power Modes

The USCI module provides automatic clock activation for SMCLK for use with low-power modes. When SMCLK is the USCI clock source, and is inactive because the device is in a low-power mode, the USCI module automatically activates it when needed, regardless of the control-bit settings for the clock source. The clock remains active until the USCI module returns to its idle condition. After the USCI module returns to the idle condition, control of the clock source reverts to the settings of its control bits. Automatic clock activation is not provided for ACLK.

When the USCI module activates an inactive clock source, the clock source becomes active for the whole device and any peripheral configured to use the clock source may be affected. For example, a timer using SMCLK will increment while the USCI module forces SMCLK active.

12.3.15 USCI Interrupts

The USCI has one interrupt vector for transmission and one interrupt vector for reception.

USCI Transmit Interrupt Operation

The UCAtXIFG interrupt flag is set by the transmitter to indicate that UCAtXBUF is ready to accept another character. An interrupt request is generated if UCAtXIE and GIE are also set. UCAtXIFG is automatically reset if a character is written to UCAtXBUF.

UCAtXIFG is set after a PUC or when UCSWRST = 1. UCAtXIE is reset after a PUC or when UCSWRST = 1.

USCI Receive Interrupt Operation

The UCARXIFG interrupt flag is set each time a character is received and loaded into UCARXBUF. An interrupt request is generated if UCARXIE and GIE are also set. UCARXIFG and UCARXIE are reset by a system reset PUC signal or when UCSWRST = 1. UCARXIFG is automatically reset when UCARXBUF is read.

Additional interrupt control features include:

- ☐ When UCARXEIE = 0 erroneous characters will not set UCARXIFG.
- ☐ When UCDORM = 1, non-address characters will not set UCARXIFG in multiprocessor modes.
- ☐ When UCBRKIE = 1 a break condition will set the UCBRK bit and the UCARXIFG flag.

USCI Interrupt Usage

USCI_Ax and USCI_Bx share the same interrupt vectors. The receive interrupt flags UCAxRXIFG and UCBxRXIFG are routed to one interrupt vector, the transmit interrupt flags UCAxTXIFG and UCBxTXIFG share another interrupt vector.

Shared Interrupt Vectors Software Example

The following software example shows an extract of an interrupt service routine to handle data receive interrupts from USCI_A0 in either UART or SPI mode and USCI_B0 in SPI mode.

```
USCIA0_RX_USCIB0_RX_ISR
    BIT.B #UCA0RXIFG, &IFG2 ; USCI_A0 Receive Interrupt?
    JNZ    USCIA0_RX_ISR
USCIB0_RX_ISR?
    ; Read UCB0RXBUF (clears UCB0RXIFG)
    ...
    RETI
USCIA0_RX_ISR
    ; Read UCA0RXBUF (clears UCA0RXIFG)
    ...
    RETI
```

The following software example shows an extract of an interrupt service routine to handle data transmit interrupts from USCI_A0 in either UART or SPI mode and USCI_B0 in SPI mode.

```
USCIA0_TX_USCIB0_TX_ISR
    BIT.B #UCA0TXIFG, &IFG2 ; USCI_A0 Transmit Interrupt?
    JNZ    USCIA0_TX_ISR
USCIB0_TX_ISR
    ; Write UCB0TXBUF (clears UCB0TXIFG)
    ...
    RETI
USCIA0_TX_ISR
    ; Write UCA0TXBUF (clears UCA0TXIFG)
    ...
    RETI
```

12.4 USCI Registers: UART Mode

The USCI registers applicable in UART mode are listed in Table 12–6 and Table 12–7.

Table 12–6. USCI_A0 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_A0 control register 0	UCA0CTL0	Read/write	060h	Reset with PUC
USCI_A0 control register 1	UCA0CTL1	Read/write	061h	001h with PUC
USCI_A0 Baud rate control register 0	UCA0BR0	Read/write	062h	Reset with PUC
USCI_A0 Baud rate control register 1	UCA0BR1	Read/write	063h	Reset with PUC
USCI_A0 modulation control register	UCA0MCTL	Read/write	064h	Reset with PUC
USCI_A0 status register	UCA0STAT	Read/write	065h	Reset with PUC
USCI_A0 Receive buffer register	UCA0RXBUF	Read	066h	Reset with PUC
USCI_A0 Transmit buffer register	UCA0TXBUF	Read/write	067h	Reset with PUC
USCI_A0 Auto Baud control register	UCA0ABCTL	Read/write	05Dh	Reset with PUC
USCI_A0 IrDA Transmit control register	UCA0IRTCTL	Read/write	05Eh	Reset with PUC
USCI_A0 IrDA Receive control register	UCA0IRRCTL	Read/write	05Fh	Reset with PUC
SFR interrupt enable register 2	IE2	Read/write	001h	Reset with PUC
SFR interrupt flag register 2	IFG2	Read/write	003h	00Ah with PUC

Note: Modifying SFR bits

To avoid modifying control bits of other modules, it is recommended to set or clear the IEx and IFGx bits using `BIS.B` or `BIC.B` instructions, rather than `MOV.B` or `CLR.B` instructions.

Table 12–7. USCI_A1 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_A1 control register 0	UCA1CTL0	Read/write	0D0h	Reset with PUC
USCI_A1 control register 1	UCA1CTL1	Read/write	0D1h	001h with PUC
USCI_A1 Baud rate control register 0	UCA1BR0	Read/write	0D2h	Reset with PUC
USCI_A1 Baud rate control register 1	UCA1BR1	Read/write	0D3h	Reset with PUC
USCI_A1 modulation control register	UCA10MCTL	Read/write	0D4h	Reset with PUC
USCI_A1 status register	UCA1STAT	Read/write	0D5h	Reset with PUC
USCI_A1 Receive buffer register	UCA1RXBUF	Read	0D6h	Reset with PUC
USCI_A1 Transmit buffer register	UCA1TXBUF	Read/write	0D7h	Reset with PUC
USCI_A1 Auto Baud control register	UCA1ABCTL	Read/write	0CDh	Reset with PUC
USCI_A1 IrDA Transmit control register	UCA1IRTCTL	Read/write	0CEh	Reset with PUC
USCI_A1 IrDA Receive control register	UCA1IRRCTL	Read/write	0CFh	Reset with PUC
USCI_A1/B1 interrupt enable register	UC1IE	Read/write	006h	Reset with PUC
USCI_A1/B1 interrupt flag register	UC1IFG	Read/write	007h	00Ah with PUC

UCAxCTL0, USCI_Ax Control Register 0

7	6	5	4	3	2	1	0
UCPEN	UCPAR	UCMSB	UC7BIT	UCSPB	UCMODEx	UCSYNC=0	
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0

UCPEN	Bit 7	Parity enable 0 Parity disabled. 1 Parity enabled. Parity bit is generated (UCAxTXD) and expected (UCAxRXD). In address-bit multiprocessor mode, the address bit is included in the parity calculation.
UCPAR	Bit 6	Parity select. UCPAR is not used when parity is disabled. 0 Odd parity 1 Even parity
UCMSB	Bit 5	MSB first select. Controls the direction of the receive and transmit shift register. 0 LSB first 1 MSB first
UC7BIT	Bit 4	Character length. Selects 7-bit or 8-bit character length. 0 8-bit data 1 7-bit data
UCSPB	Bit 3	Stop bit select. Number of stop bits. 0 One stop bit 1 Two stop bits
UCMODEx	Bits 2–1	USCI mode. The UCMODEx bits select the asynchronous mode when UCSYNC = 0. 00 UART Mode. 01 Idle-Line Multiprocessor Mode. 10 Address-Bit Multiprocessor Mode. 11 UART Mode with automatic baud rate detection.
UCSYNC	Bit 0	Synchronous mode enable 0 Asynchronous mode 1 Synchronous Mode

UCAxCTL1, USCI_Ax Control Register 1

7	6	5	4	3	2	1	0
UCSSELx		UCRXEIE	UCBRKIE	UCDORM	UCTXADDR	UCTXBRK	UCSWRST
rw-0		rw-0	rw-0	rw-0	rw-0	rw-0	rw-1

UCSSELx	Bits 7-6	USCI clock source select. These bits select the BRCLK source clock. 00 UCLK 01 ACLK 10 SMCLK 11 SMCLK
UCRXEIE	Bit 5	Receive erroneous-character interrupt-enable 0 Erroneous characters rejected and UCAxRXIFG is not set 1 Erroneous characters received will set UCAxRXIFG
UCBRKIE	Bit 4	Receive break character interrupt-enable 0 Received break characters do not set UCAxRXIFG. 1 Received break characters set UCAxRXIFG.
UCDORM	Bit 3	Dormant. Puts USCI into sleep mode. 0 Not dormant. All received characters will set UCAxRXIFG. 1 Dormant. Only characters that are preceded by an idle-line or with address bit set will set UCAxRXIFG. In UART mode with automatic baud rate detection only the combination of a break and synch field will set UCAxRXIFG.
UCTXADDR	Bit 2	Transmit address. Next frame to be transmitted will be marked as address depending on the selected multiprocessor mode. 0 Next frame transmitted is data 1 Next frame transmitted is an address
UCTXBRK	Bit 1	Transmit break. Transmits a break with the next write to the transmit buffer. In UART mode with automatic baud rate detection 055h must be written into UCAxTXBUF to generate the required break/synch fields. Otherwise 0h must be written into the transmit buffer. 0 Next frame transmitted is not a break 1 Next frame transmitted is a break or a break/synch
UCSWRST	Bit 0	Software reset enable 0 Disabled. USCI reset released for operation. 1 Enabled. USCI logic held in reset state.

UCAxBR0, USCI_Ax Baud Rate Control Register 0

UCAxBR1, USCI_Ax Baud Rate Control Register 1

UCBRx Clock prescaler setting of the Baud rate generator.

UCAxMCTL, USCI_Ax Modulation Control Register

UCBRFx	Bits 7–4	First modulation stage select. These bits determine the modulation pattern for BITCLK16 when UCOS16 = 1. Ignored with UCOS16 = 0. Table 12–3 shows the modulation pattern.
UCBRSx	Bits 3–1	Second modulation stage select. These bits determine the modulation pattern for BITCLK. Table 12–2 shows the modulation pattern.
UCOS16	Bit 0	Oversampling mode enabled 0 Disabled 1 Enabled

UCAxSTAT, USCI_Ax Status Register

7	6	5	4	3	2	1	0
UCLISTEN	UCFE	UCOE	UCPE	UCBRK	UCRXERR	UCADDR UCIDLE	UCBUSY
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	r-0

UCLISTEN	Bit 7	Listen enable. The UCLISTEN bit selects loopback mode. 0 Disabled 1 Enabled. UCAxTXD is internally fed back to the receiver.
UCFE	Bit 6	Framing error flag 0 No error 1 Character received with low stop bit
UCOE	Bit 5	Overrun error flag. This bit is set when a character is transferred into UCAxRXBUF before the previous character was read. UCOE is cleared automatically when UCxRXBUF is read, and must not be cleared by software. Otherwise, it will not function correctly. 0 No error 1 Overrun error occurred
UCPE	Bit 4	Parity error flag. When UCPEN = 0, UCPE is read as 0. 0 No error 1 Character received with parity error
UCBRK	Bit 3	Break detect flag 0 No break condition 1 Break condition occurred
UCRXERR	Bit 2	Receive error flag. This bit indicates a character was received with error(s). When UCRXERR = 1, on or more error flags (UCFE, UCPE, UCOE) is also set. UCRXERR is cleared when UCAxRXBUF is read. 0 No receive errors detected 1 Receive error detected
UCADDR	Bit 1	Address received in address-bit multiprocessor mode. 0 Received character is data 1 Received character is an address
UCIDLE		Idle line detected in idle-line multiprocessor mode. 0 No idle line detected 1 Idle line detected
UCBUSY	Bit 0	USCI busy. This bit indicates if a transmit or receive operation is in progress. 0 USCI inactive 1 USCI transmitting or receiving

UCAxRXBUF, USCI_Ax Receive Buffer Register

UCRXBUFx Bits The receive-data buffer is user accessible and contains the last received character from the receive shift register. Reading UCAxRXBUF resets the receive-error bits, the UCADDR or UCIDLE bit, and UCAxRXIFG. In 7-bit data mode, UCAxRXBUF is LSB justified and the MSB is always reset.

7–0

UCAxTXBUF, USCI_Ax Transmit Buffer Register

UCTXBUFx Bits The transmit data buffer is user accessible and holds the data waiting to be moved into the transmit shift register and transmitted on UCAxTXD. Writing to the transmit data buffer clears UCAxTXIFG. The MSB of UCAxTXBUF is not used for 7-bit data and is reset.

7–0

UCAxIRTCTL, USCI_Ax IrDA Transmit Control Register

UCIRTXPLx	Bits	Transmit pulse length
	7-2	Pulse Length $t_{PULSE} = (UCIRTXPLx + 1) / (2 * f_{IRTCLK})$
UCIRTXCLK	Bit 1	IrDA transmit pulse clock select
	0	BRCLK
	1	BITCLK16 when UCOS16 = 1. Otherwise, BRCLK
UCIREN	Bit 0	IrDA encoder/decoder enable.
	0	IrDA encoder/decoder disabled
	1	IrDA encoder/decoder enabled

UCAxIRRCTL, USCI_Ax IrDA Receive Control Register

UCIRRFLx	Bits	Receive filter length. The minimum pulse length for receive is given by:
	7-2	$t_{MIN} = (UCIRRFLx + 4) / (2 * f_{IRTCLK})$
UCIRRXP	Bit 1	IrDA receive input UCAxRXD polarity
	0	IrDA transceiver delivers a high pulse when a light pulse is seen
	1	IrDA transceiver delivers a low pulse when a light pulse is seen
UCIRRXFE	Bit 0	IrDA receive filter enabled
	0	Receive filter disabled
	1	Receive filter enabled

UCAxABCTL, USCI_Ax Auto Baud Rate Control Register

7	6	5	4	3	2	1	0
Reserved		UCDELIMx		UCSTOE	UCBTOE	Reserved	UCABDEN
r-0		rw-0		rw-0	rw-0	r-0	rw-0

Reserved	Bits 7-6	Reserved
UCDELIMx	Bits 5-4	Break/synch delimiter length 00 1 bit time 01 2 bit times 10 3 bit times 11 4 bit times
UCSTOE	Bit 3	Synch field time out error 0 No error 1 Length of synch field exceeded measurable time.
UCBTOE	Bit 2	Break time out error 0 No error 1 Length of break field exceeded 22 bit times.
Reserved	Bit 1	Reserved
UCABDEN	Bit 0	Automatic baud rate detect enable 0 Baud rate detection disabled. Length of break and synch field is not measured. 1 Baud rate detection enabled. Length of break and synch field is measured and baud rate settings are changed accordingly.

IE2, Interrupt Enable Register 2

7	6	5	4	3	2	1	0
						UCA0TXIE	UCA0RXIE
						rw-0	rw-0

Bits 7-2 These bits may be used by other modules. See device-specific datasheet.

Universal Serial Communication Interface, SPI Mode

The universal serial communication interface (USCI) supports multiple serial communication modes with one hardware module. This chapter discusses the operation of the synchronous peripheral interface or SPI mode.

Topic	Page
13.1 USCI Overview	13-2
13.2 USCI Introduction: SPI Mode	13-3
13.3 USCI Operation: SPI Mode	13-5
13.4 USCI Registers: SPI Mode	13-15

13.1 USCI Overview

The universal serial communication interface (USCI) modules support multiple serial communication modes. Different USCI modules support different modes. Each different USCI module is named with a different letter. For example, USCI_A is different from USCI_B, etc. If more than one identical USCI module is implemented on one device, those modules are named with incrementing numbers. For example, if one device has two USCI_A modules, they are named USCI_A0 and USCI_A1. See the device-specific datasheet to determine which USCI modules, if any, are implemented on which devices.

The USCI_Ax modules support:

- ☐ UART mode
- ☐ Pulse shaping for IrDA communications
- ☐ Automatic baud rate detection for LIN communications
- ☐ SPI mode

The USCI_Bx modules support:

- ☐ I²C mode
- ☐ SPI mode

13.2 USCI Introduction: SPI Mode

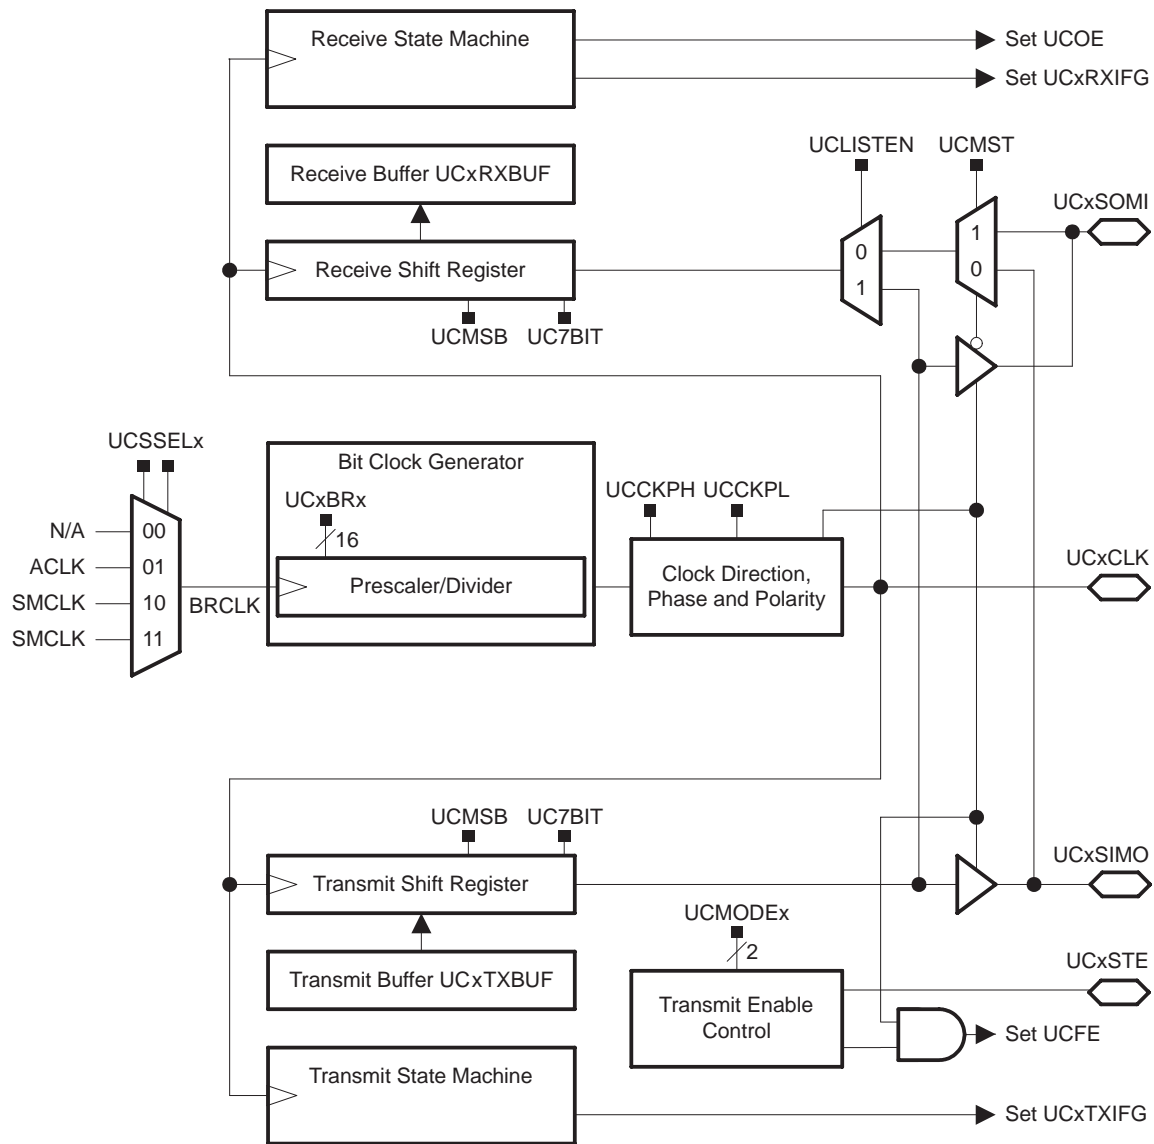

In synchronous mode, the USCI connects the MSP430 to an external system via three or four pins: UCxSIMO, UCxSOMI, UCxCLK, and UCxSTE. SPI mode is selected when the UCSYNC bit is set and SPI mode (3-pin or 4-pin) is selected with the UCMODEx bits.

SPI mode features include:

- ☐ 7- or 8-bit data length
- ☐ LSB-first or MSB-first data transmit and receive
- ☐ 3-pin and 4-pin SPI operation
- ☐ Master or slave modes
- ☐ Independent transmit and receive shift registers
- ☐ Separate transmit and receive buffer registers
- ☐ Continuous transmit and receive operation
- ☐ Selectable clock polarity and phase control
- ☐ Programmable clock frequency in master mode
- ☐ Independent interrupt capability for receive and transmit
- ☐ Slave operation in LPM4

Figure 13–1 shows the USCI when configured for SPI mode.

Figure 13–1. USCI Block Diagram: SPI Mode

13.3 USCI Operation: SPI Mode

In SPI mode, serial data is transmitted and received by multiple devices using a shared clock provided by the master. An additional pin, UCxSTE, is provided to enable a device to receive and transmit data and is controlled by the master.

Three or four signals are used for SPI data exchange:

- ☐ UCxSIMO Slave in, master out
Master mode: UCxSIMO is the data output line.
Slave mode: UCxSIMO is the data input line.
- ☐ UCxSOMI Slave out, master in
Master mode: UCxSOMI is the data input line.
Slave mode: UCxSOMI is the data output line.
- ☐ UCxCLK USCI SPI clock
Master mode: UCxCLK is an output.
Slave mode: UCxCLK is an input.
- ☐ UCxSTE Slave transmit enable. Used in 4-pin mode to allow multiple masters on a single bus. Not used in 3-pin mode. Table 13–1 describes the UCxSTE operation.

Table 13–1. UCxSTE Operation

UCMODEx	UCxSTE Active State	UCxSTE	Slave	Master
01	high	0	inactive	active
		1	active	inactive
10	low	0	active	inactive
		1	inactive	active

13.3.1 USCI Initialization and Reset

The USCI is reset by a PUC or by the UCSWRST bit. After a PUC, the UCSWRST bit is automatically set, keeping the USCI in a reset condition. When set, the UCSWRST bit resets the UCxRXIE, UCxTXIE, UCxRXIFG, UCOE, and UCFE bits and sets the UCxTXIFG flag. Clearing UCSWRST releases the USCI for operation.

Note: Initializing or Re-Configuring the USCI Module

The recommended USCI initialization/re-configuration process is:

- 1) Set UCSWRST (`BIS.B #UCSWRST, &UCxCTL1`)
 - 2) Initialize all USCI registers with UCSWRST=1 (including UCxCTL1)
 - 3) Configure ports.
 - 4) Clear UCSWRST via software (`BIC.B #UCSWRST, &UCxCTL1`)
 - 5) Enable interrupts (optional) via UCxRXIE and/or UCxTXIE
-

13.3.2 Character Format

The USCI module in SPI mode supports 7- and 8-bit character lengths selected by the UC7BIT bit. In 7-bit data mode, UCxRXBUF is LSB justified and the MSB is always reset. The UCMSB bit controls the direction of the transfer and selects LSB or MSB first.

Note: Default Character Format

The default SPI character transmission is LSB first. For communication with other SPI interfaces it MSB-first mode may be required.

Note: Character Format for Figures

Figures throughout this chapter use MSB first format.

13.3.3 Master Mode

Figure 13–2. USCI Master and External Slave

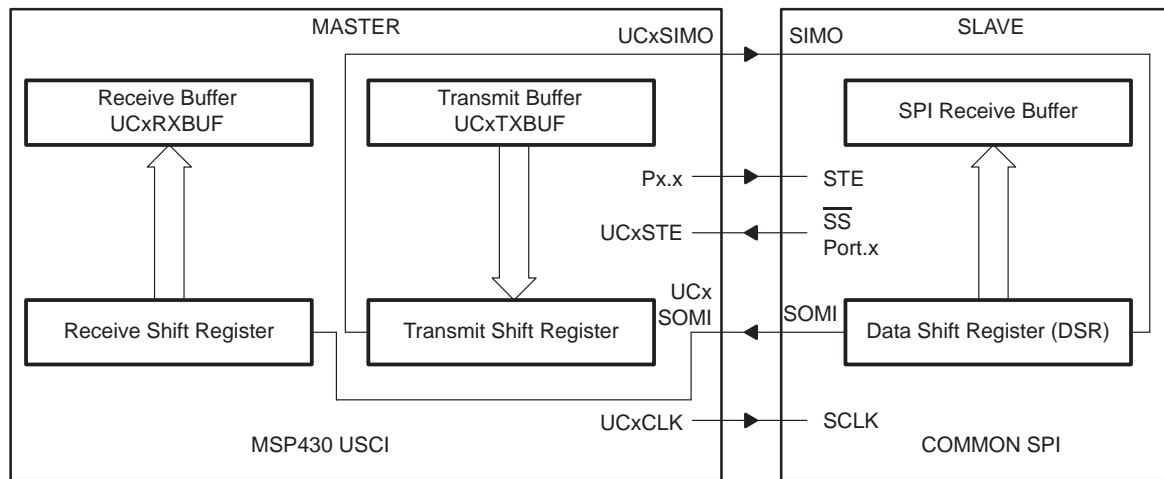

Figure 13–2 shows the USCI as a master in both 3-pin and 4-pin configurations. The USCI initiates data transfer when data is moved to the transmit data buffer UCxTXBUF. The UCxTXBUF data is moved to the TX shift register when the TX shift register is empty, initiating data transfer on UCxSIMO starting with either the most-significant or least-significant bit depending on the UCMSB setting. Data on UCxSOMI is shifted into the receive shift register on the opposite clock edge. When the character is received, the receive data is moved from the RX shift register to the received data buffer UCxRXBUF and the receive interrupt flag, UCxRXIFG, is set, indicating the RX/TX operation is complete.

A set transmit interrupt flag, UCxTXIFG, indicates that data has moved from UCxTXBUF to the TX shift register and UCxTXBUF is ready for new data. It does not indicate RX/TX completion.

To receive data into the USCI in master mode, data must be written to UCxTXBUF because receive and transmit operations operate concurrently.

Four-Pin SPI Master Mode

In 4-pin master mode, UCxSTE is used to prevent conflicts with another master and controls the master as described in Table 13–1. When UCxSTE is in the master-inactive state:

- ☐ UCxSIMO and UCxCLK are set to inputs and no longer drive the bus
- ☐ The error bit UCFE is set indicating a communication integrity violation to be handled by the user.
- ☐ The internal state machines are reset and the shift operation is aborted.

If data is written into UCxTXBUF while the master is held inactive by UCxSTE, it will be transmit as soon as UCxSTE transitions to the master-active state. If an active transfer is aborted by UCxSTE transitioning to the master-inactive state, the data must be re-written into UCxTXBUF to be transferred when UCxSTE transitions back to the master-active state. The UCxSTE input signal is not used in 3-pin master mode.

13.3.4 Slave Mode

Figure 13–3. USCI Slave and External Master

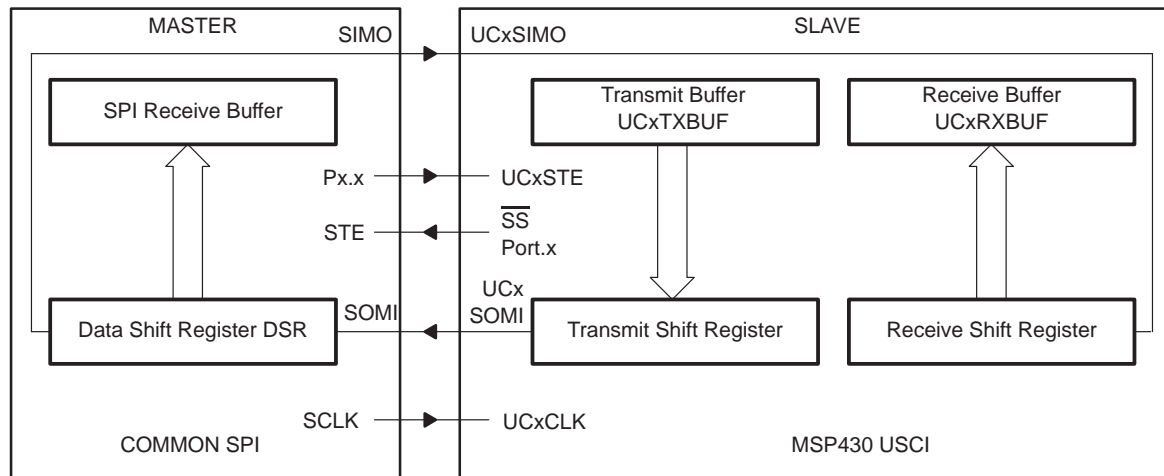

Figure 13–3 shows the USCI as a slave in both 3-pin and 4-pin configurations. UCxCLK is used as the input for the SPI clock and must be supplied by the external master. The data-transfer rate is determined by this clock and not by the internal bit clock generator. Data written to UCxTXBUF and moved to the TX shift register before the start of UCxCLK is transmitted on UCxSOMI. Data on UCxSIMO is shifted into the receive shift register on the opposite edge of UCxCLK and moved to UCxRXBUF when the set number of bits are received. When data is moved from the RX shift register to UCxRXBUF, the UCxRXIFG interrupt flag is set, indicating that data has been received. The overrun error bit, UCOE, is set when the previously received data is not read from UCxRXBUF before new data is moved to UCxRXBUF.

Four-Pin SPI Slave Mode

In 4-pin slave mode, UCxSTE is used by the slave to enable the transmit and receive operations and is provided by the SPI master. When UCxSTE is in the slave-active state, the slave operates normally. When UCxSTE is in the slave-inactive state:

- ☐ Any receive operation in progress on UCxSIMO is halted
- ☐ UCxSOMI is set to the input direction
- ☐ The shift operation is halted until the UCxSTE line transitions into the slave transmit active state.

The UCxSTE input signal is not used in 3-pin slave mode.

13.3.5 SPI Enable

When the USCI module is enabled by clearing the UCSWRST bit it is ready to receive and transmit. In master mode the bit clock generator is ready, but is not clocked nor producing any clocks. In slave mode the bit clock generator is disabled and the clock is provided by the master.

A transmit or receive operation is indicated by UCBUSY = 1.

A PUC or set UCSWRST bit disables the USCI immediately and any active transfer is terminated.

Transmit Enable

In master mode, writing to UCxTXBUF activates the bit clock generator and the data will begin to transmit.

In slave mode, transmission begins when a master provides a clock and, in 4-pin mode, when the UCxSTE is in the slave-active state.

Receive Enable

The SPI receives data when a transmission is active. Receive and transmit operations operate concurrently.

13.3.6 Serial Clock Control

UCxCLK is provided by the master on the SPI bus. When UCMST = 1, the bit clock is provided by the USCI bit clock generator on the UCxCLK pin. The clock used to generate the bit clock is selected with the UCSSELx bits. When UCMST = 0, the USCI clock is provided on the UCxCLK pin by the master, the bit clock generator is not used, and the UCSSELx bits are don't care. The SPI receiver and transmitter operate in parallel and use the same clock source for data transfer.

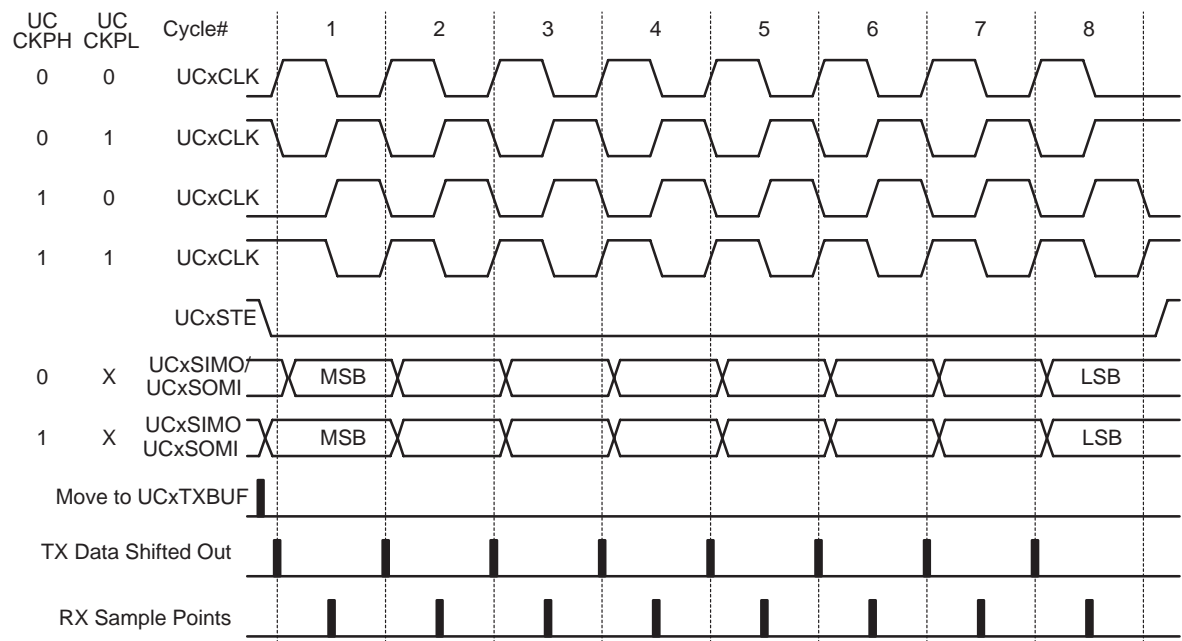

The 16-bit value of UCBRx in the bit rate control registers UCxxBR1 and UCxxBR0 is the division factor of the USCI clock source, BRCLK. The maximum bit clock that can be generated in master mode is BRCLK. Modulation is not used in SPI mode and UCAxMCTL should be cleared when using SPI mode for USCI_A. The UCAxCLK/UCBxCLK frequency is given by:

$$f_{\text{BitClock}} = \frac{f_{\text{BRCLK}}}{\text{UCBRx}}$$

Serial Clock Polarity and Phase

The polarity and phase of UCxCLK are independently configured via the UCCKPL and UCCKPH control bits of the USCI. Timing for each case is shown in Figure 13–4.

Figure 13–4. USCI SPI Timing with UCMSB = 1

13.3.7 Using the SPI Mode with Low Power Modes

The USCI module provides automatic clock activation for SMCLK for use with low-power modes. When SMCLK is the USCI clock source, and is inactive because the device is in a low-power mode, the USCI module automatically activates it when needed, regardless of the control-bit settings for the clock source. The clock remains active until the USCI module returns to its idle condition. After the USCI module returns to the idle condition, control of the clock source reverts to the settings of its control bits. Automatic clock activation is not provided for ACLK.

When the USCI module activates an inactive clock source, the clock source becomes active for the whole device and any peripheral configured to use the clock source may be affected. For example, a timer using SMCLK will increment while the USCI module forces SMCLK active.

In SPI slave mode no internal clock source is required because the clock is provided by the external master. It is possible to operate the USCI in SPI slave mode while the device is in LPM4 and all clock sources are disabled. The receive or transmit interrupt can wake up the CPU from any low power mode.

13.3.8 SPI Interrupts

The USCI has one interrupt vector for transmission and one interrupt vector for reception.

SPI Transmit Interrupt Operation

The UCxTXIFG interrupt flag is set by the transmitter to indicate that UCxTXBUF is ready to accept another character. An interrupt request is generated if UCxTXIE and GIE are also set. UCxTXIFG is automatically reset if a character is written to UCxTXBUF. UCxTXIFG is set after a PUC or when UCSWRST = 1. UCxTXIE is reset after a PUC or when UCSWRST = 1.

Note: Writing to UCxTXBUF in SPI Mode

Data written to UCxTXBUF when UCxTXIFG = 0 may result in erroneous data transmission.

SPI Receive Interrupt Operation

The UCxRXIFG interrupt flag is set each time a character is received and loaded into UCxRXBUF. An interrupt request is generated if UCxRXIE and GIE are also set. UCxRXIFG and UCxRXIE are reset by a system reset PUC signal or when UCSWRST = 1. UCxRXIFG is automatically reset when UCxRXBUF is read.

USCI Interrupt Usage

USCI_Ax and USCI_Bx share the same interrupt vectors. The receive interrupt flags UCAxRXIFG and UCBxRXIFG are routed to one interrupt vector, the transmit interrupt flags UCAxTXIFG and UCBxTXIFG share another interrupt vector.

Shared Interrupt Vectors Software Example

The following software example shows an extract of an interrupt service routine to handle data receive interrupts from USCI_A0 in either UART or SPI mode and USCI_B0 in SPI mode.

```
USCIA0_RX_USCIB0_RX_ISR
    BIT.B #UCA0RXIFG, &IFG2 ; USCI_A0 Receive Interrupt?
    JNZ   USCIA0_RX_ISR
USCIB0_RX_ISR?
    ; Read UCB0RXBUF (clears UCB0RXIFG)
    ...
    RETI
USCIA0_RX_ISR
    ; Read UCA0RXBUF (clears UCA0RXIFG)
    ...
    RETI
```

The following software example shows an extract of an interrupt service routine to handle data transmit interrupts from USCI_A0 in either UART or SPI mode and USCI_B0 in SPI mode.

```
USCIA0_TX_USCIB0_TX_ISR
    BIT.B #UCA0TXIFG, &IFG2 ; USCI_A0 Transmit Interrupt?
    JNZ   USCIA0_TX_ISR
USCIB0_TX_ISR
    ; Write UCB0TXBUF (clears UCB0TXIFG)
    ...
    RETI
USCIA0_TX_ISR
    ; Write UCA0TXBUF (clears UCA0TXIFG)
    ...
    RETI
```

13.4 USCI Registers: SPI Mode

The USCI registers applicable in SPI mode for USCI_A0 and USCI_B0 are listed in Table 13–2. Registers applicable in SPI mode for USCI_A1 and USCI_B1 are listed in Table 13–3.

Table 13–2. USCI_A0 and USCI_B0 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_A0 control register 0	UCA0CTL0	Read/write	060h	Reset with PUC
USCI_A0 control register 1	UCA0CTL1	Read/write	061h	001h with PUC
USCI_A0 Baud rate control register 0	UCA0BR0	Read/write	062h	Reset with PUC
USCI_A0 Baud rate control register 1	UCA0BR1	Read/write	063h	Reset with PUC
USCI_A0 modulation control register	UCA0MCTL	Read/write	064h	Reset with PUC
USCI_A0 status register	UCA0STAT	Read/write	065h	Reset with PUC
USCI_A0 Receive buffer register	UCA0RXBUF	Read	066h	Reset with PUC
USCI_A0 Transmit buffer register	UCA0TXBUF	Read/write	067h	Reset with PUC
USCI_B0 control register 0	UCB0CTL0	Read/write	068h	001h with PUC
USCI_B0 control register 1	UCB0CTL1	Read/write	069h	001h with PUC
USCI_B0 Bit rate control register 0	UCB0BR0	Read/write	06Ah	Reset with PUC
USCI_B0 Bit rate control register 1	UCB0BR1	Read/write	06Bh	Reset with PUC
USCI_B0 status register	UCB0STAT	Read/write	06Dh	Reset with PUC
USCI_B0 Receive buffer register	UCB0RXBUF	Read	06Eh	Reset with PUC
USCI_B0 Transmit buffer register	UCB0TXBUF	Read/write	06Fh	Reset with PUC
SFR interrupt enable register 2	IE2	Read/write	001h	Reset with PUC
SFR interrupt flag register 2	IFG2	Read/write	003h	00Ah with PUC

Note: Modifying SFR bits

To avoid modifying control bits of other modules, it is recommended to set or clear the IEx and IFGx bits using `BIS.B` or `BIC.B` instructions, rather than `MOV.B` or `CLR.B` instructions.

Table 13–3. USCI_A1 and USCI_B1 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_A1 control register 0	UCA1CTL0	Read/write	0D0h	Reset with PUC

Universal Serial Communication Interface, I²C Mode

The universal serial communication interface (USCI) supports multiple serial communication modes with one hardware module. This chapter discusses the operation of the I²C mode.

Topic	Page
14.1 USCI Overview	14-2
14.2 USCI Introduction: I2C Mode	14-3
14.3 USCI Operation: I2C Mode	14-5
14.4 USCI Registers: I2C Mode	14-25

14.1 USCI Overview

The universal serial communication interface (USCI) modules support multiple serial communication modes. Different USCI modules support different modes. Each different USCI module is named with a different letter. For example, USCI_A is different from USCI_B, etc. If more than one identical USCI module is implemented on one device, those modules are named with incrementing numbers. For example, if one device has two USCI_A modules, they are named USCI_A0 and USCI_A1. See the device-specific datasheet to determine which USCI modules, if any, are implemented on which devices.

The USCI_Ax modules support:

- ☐ UART mode
- ☐ Pulse shaping for IrDA communications
- ☐ Automatic baud rate detection for LIN communications
- ☐ SPI mode

The USCI_Bx modules support:

- ☐ I²C mode
- ☐ SPI mode

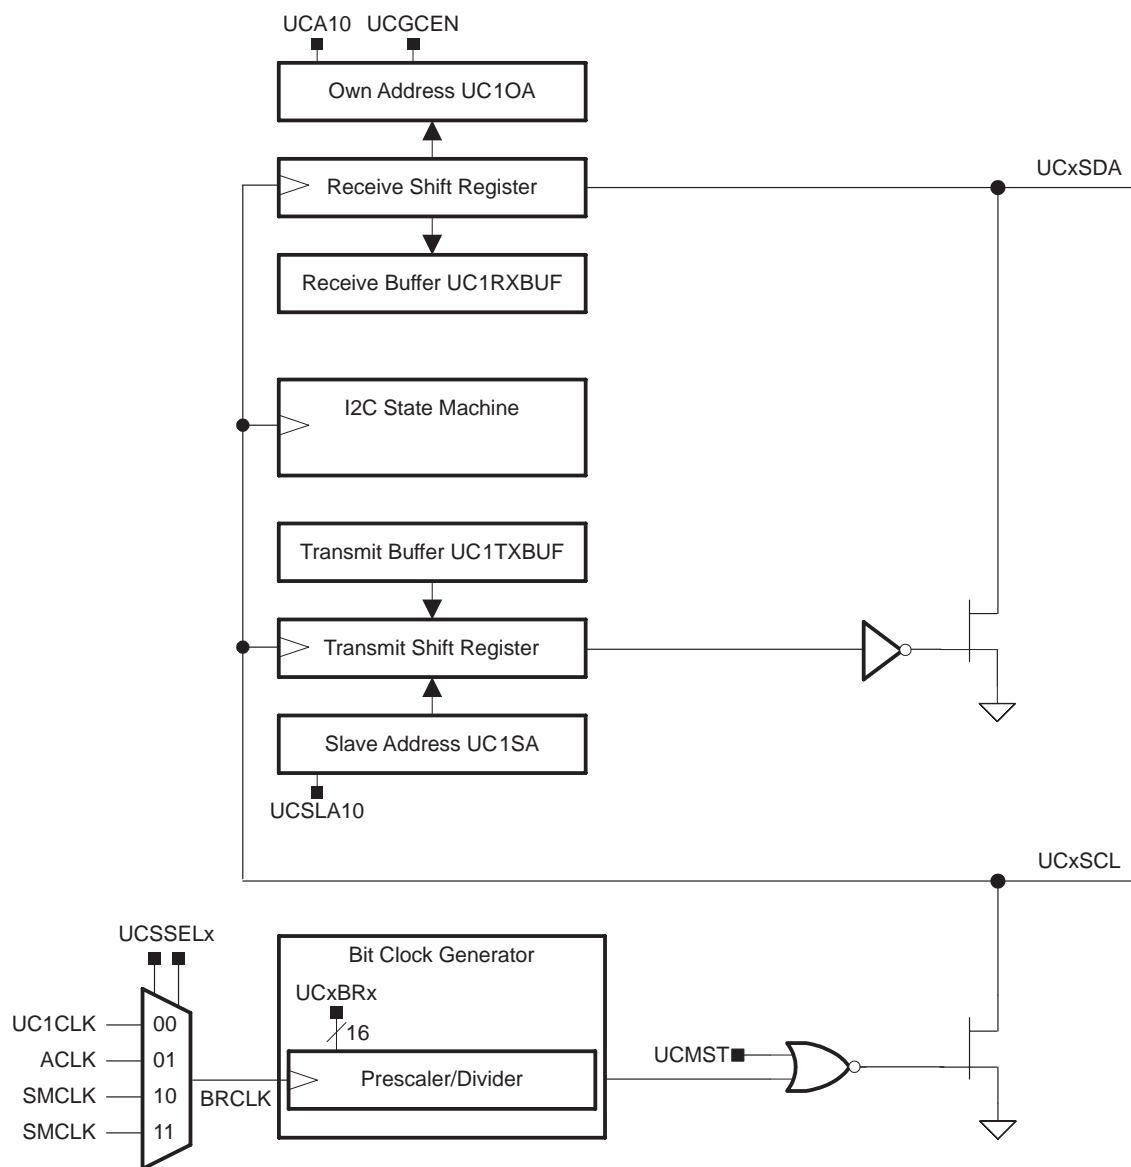

14.2 USCI Introduction: I²C Mode

In I²C mode, the USCI module provides an interface between the MSP430 and I²C-compatible devices connected by way of the two-wire I²C serial bus. External components attached to the I²C bus serially transmit and/or receive serial data to/from the USCI module through the 2-wire I²C interface.

The I²C mode features include:

- ☐ Compliance to the Philips Semiconductor I²C specification v2.1
 - 7-bit and 10-bit device addressing modes
 - General call
 - START/RESTART/STOP
 - Multi-master transmitter/receiver mode
 - Slave receiver/transmitter mode
 - Standard mode up to 100 kbps and fast mode up to 400 kbps support
- ☐ Programmable UCxCLK frequency in master mode
- ☐ Designed for low power
- ☐ Slave receiver START detection for auto-wake up from LPMx modes
- ☐ Slave operation in LPM4

Figure 14–1 shows the USCI when configured in I²C mode.

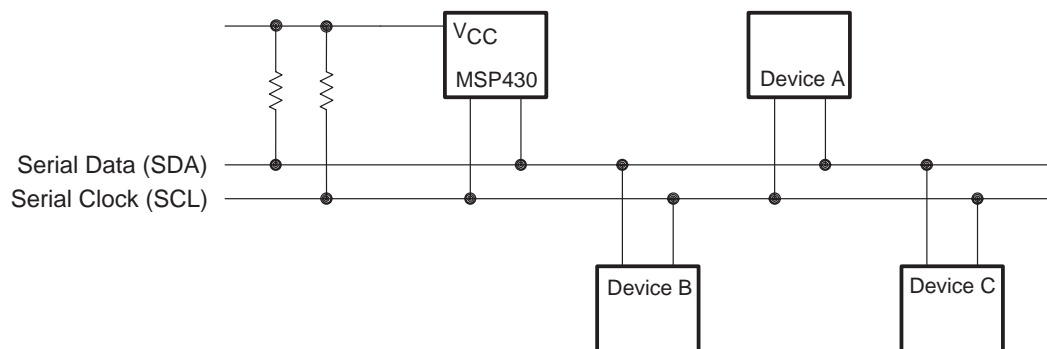

Figure 14–1. USCI Block Diagram: I²C Mode

14.3 USCI Operation: I²C Mode

The I²C mode supports any slave or master I²C-compatible device. Figure 14–2 shows an example of an I²C bus. Each I²C device is recognized by a unique address and can operate as either a transmitter or a receiver. A device connected to the I²C bus can be considered as the master or the slave when performing data transfers. A master initiates a data transfer and generates the clock signal SCL. Any device addressed by a master is considered a slave.

I²C data is communicated using the serial data pin (SDA) and the serial clock pin (SCL). Both SDA and SCL are bidirectional, and must be connected to a positive supply voltage using a pull-up resistor.

Figure 14–2. I²C Bus Connection Diagram

Note: SDA and SCL Levels

The MSP430 SDA and SCL pins must not be pulled up above the MSP430 V_{CC} level.

14.3.1 USCI Initialization and Reset

The USCI is reset by a PUC or by setting the UCSWRST bit. After a PUC, the UCSWRST bit is automatically set, keeping the USCI in a reset condition. To select I2C operation the UCMODEx bits must be set to 11. After module initialization, it is ready for transmit or receive operation. Clearing UCSWRST releases the USCI for operation.

Configuring and re-configuring the USCI module should be done when UCSWRST is set to avoid unpredictable behavior. Setting UCSWRST in I2C mode has the following effects:

- ☐ I2C communication stops
- ☐ SDA and SCL are high impedance
- ☐ UCBxI2CSTAT, bits 6-0 are cleared
- ☐ UCBxTXIE and UCBxRXIE are cleared
- ☐ UCBxTXIFG and UCBxRXIFG are cleared
- ☐ All other bits and registers remain unchanged.

Note: Initializing or Re-Configuring the USCI Module

The recommended USCI initialization/re-configuration process is:

- 1) Set UCSWRST (`BIS.B #UCSWRST, &UCxCTL1`)
 - 2) Initialize all USCI registers with UCSWRST=1 (including UCxCTL1)
 - 3) Configure ports.
 - 4) Clear UCSWRST via software (`BIC.B #UCSWRST, &UCxCTL1`)
 - 5) Enable interrupts (optional) via UCxRXIE and/or UCxTXIE
-

14.3.2 I²C Serial Data

One clock pulse is generated by the master device for each data bit transferred. The I²C mode operates with byte data. Data is transferred most significant bit first as shown in Figure 14–3.

The first byte after a START condition consists of a 7-bit slave address and the R/\overline{W} bit. When $R/\overline{W} = 0$, the master transmits data to a slave. When $R/\overline{W} = 1$, the master receives data from a slave. The ACK bit is sent from the receiver after each byte on the 9th SCL clock.

Figure 14–3. I²C Module Data Transfer

START and STOP conditions are generated by the master and are shown in Figure 14–3. A START condition is a high-to-low transition on the SDA line while SCL is high. A STOP condition is a low-to-high transition on the SDA line while SCL is high. The bus busy bit, UCBBUSY, is set after a START and cleared after a STOP.

Data on SDA must be stable during the high period of SCL as shown in Figure 14–4. The high and low state of SDA can only change when SCL is low, otherwise START or STOP conditions will be generated.

Figure 14–4. Bit Transfer on the I²C Bus

14.3.3 I²C Addressing Modes

The I²C mode supports 7-bit and 10-bit addressing modes.

7-Bit Addressing

In the 7-bit addressing format, shown in Figure 14–5, the first byte is the 7-bit slave address and the $\overline{R/\overline{W}}$ bit. The ACK bit is sent from the receiver after each byte.

Figure 14–5. I²C Module 7-Bit Addressing Format

10-Bit Addressing

In the 10-bit addressing format, shown in Figure 14–6, the first byte is made up of 11110b plus the two MSBs of the 10-bit slave address and the $\overline{R/\overline{W}}$ bit. The ACK bit is sent from the receiver after each byte. The next byte is the remaining 8 bits of the 10-bit slave address, followed by the ACK bit and the 8-bit data.

Figure 14–6. I²C Module 10-Bit Addressing Format

Repeated Start Conditions

The direction of data flow on SDA can be changed by the master, without first stopping a transfer, by issuing a repeated START condition. This is called a RESTART. After a RESTART is issued, the slave address is again sent out with the new data direction specified by the $\overline{R/\overline{W}}$ bit. The RESTART condition is shown in Figure 14–7.

Figure 14–7. I²C Module Addressing Format with Repeated START Condition

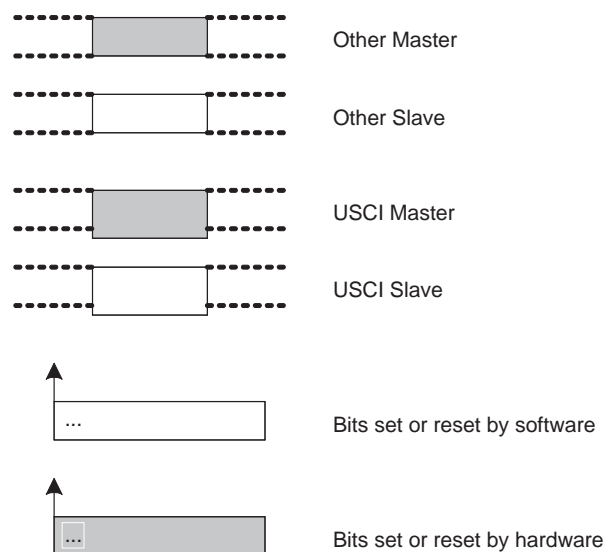

14.3.4 I²C Module Operating Modes

In I²C mode the USCI module can operate in master transmitter, master receiver, slave transmitter, or slave receiver mode. The modes are discussed in the following sections. Time lines are used to illustrate the modes.

Figure 14–8 shows how to interpret the time line figures. Data transmitted by the master is represented by grey rectangles, data transmitted by the slave by white rectangles. Data transmitted by the USCI module, either as master or slave, is shown by rectangles that are taller than the others.

Actions taken by the USCI module are shown in grey rectangles with an arrow indicating where in the the data stream the action occurs. Actions that must be handled with software are indicated with white rectangles with an arrow pointing to where in the data stream the action must take place.

Figure 14–8. I²C Time line Legend

Slave Mode

The USCI module is configured as an I²C slave by selecting the I²C mode with UCMODEx = 11 and UCSYNC = 1 and clearing the UCMST bit.

Initially the USCI module must be configured in receiver mode by clearing the UCTR bit to receive the I²C address. Afterwards, transmit and receive operations are controlled automatically depending on the R/W bit received together with the slave address.

The USCI slave address is programmed with the UCBxI2COA register. When UCA10 = 0, 7-bit addressing is selected. When UCA10 = 1, 10-bit addressing is selected. The UCGCEN bit selects if the slave responds to a general call.

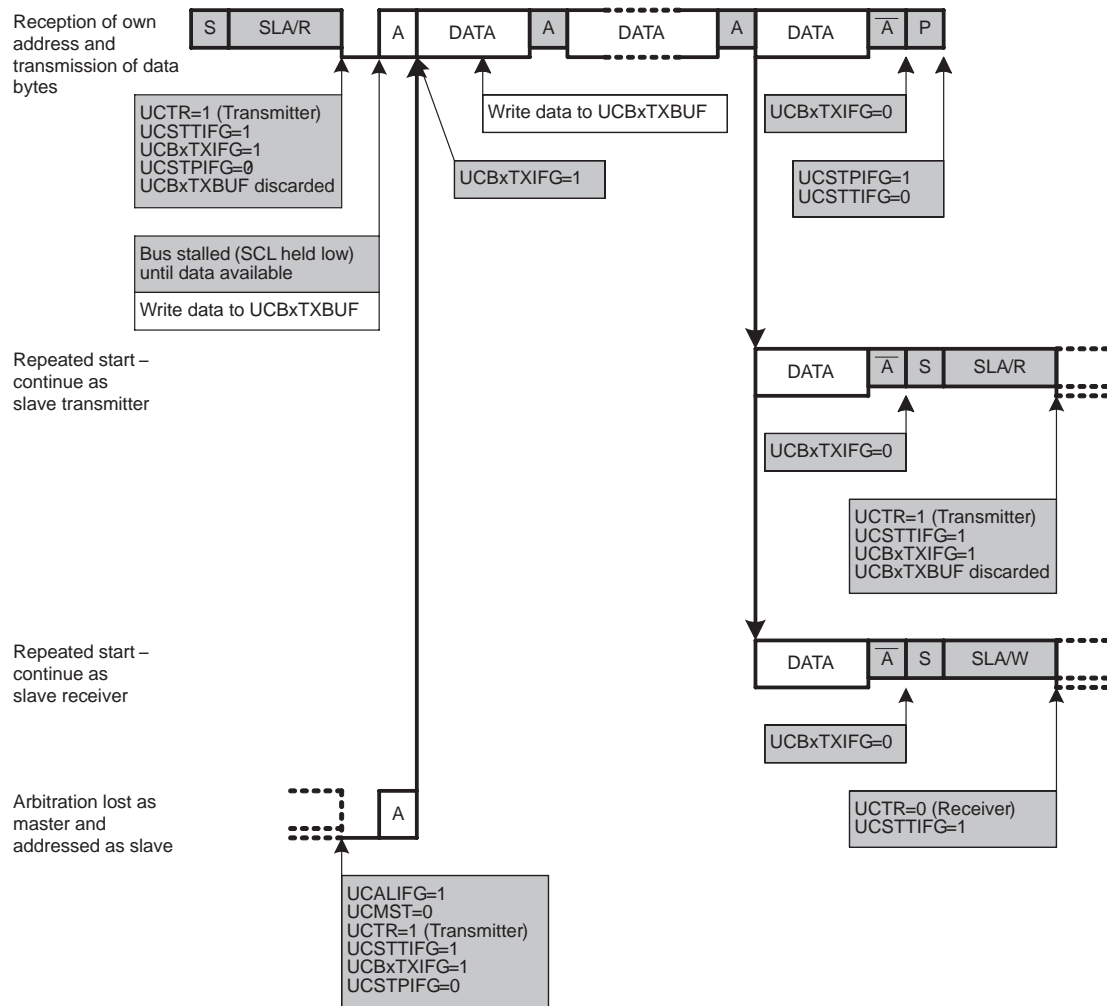

When a START condition is detected on the bus, the USCI module will receive the transmitted address and compare it against its own address stored in UCBxI2COA. The UCSTTIFG flag is set when address received matches the USCI slave address.

I²C Slave Transmitter Mode

Slave transmitter mode is entered when the slave address transmitted by the master is identical to its own address with a set R/W bit. The slave transmitter shifts the serial data out on SDA with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it will hold SCL low while intervention of the CPU is required after a byte has been transmitted.

If the master requests data from the slave the USCI module is automatically configured as a transmitter and UCTR and UCBxTXIFG become set. The SCL line is held low until the first data to be sent is written into the transmit buffer UCBxTXBUF. Then the address is acknowledged, the UCSTTIFG flag is cleared, and the data is transmitted. As soon as the data is transferred into the shift register the UCBxTXIFG is set again. After the data is acknowledged by the master the next data byte written into UCBxTXBUF is transmitted or if the buffer is empty the bus is stalled during the acknowledge cycle by holding SCL low until new data is written into UCBxTXBUF. If the master sends a NACK succeeded by a STOP condition the UCSTPIFG flag is set. If the NACK is succeeded by a repeated START condition the USCI I²C state machine returns to its address-reception state.

Figure 14–9 illustrates the slave transmitter operation.

Figure 14–9. I²C Slave Transmitter Mode

I2C Slave Receiver Mode

Slave receiver mode is entered when the slave address transmitted by the master is identical to its own address and a cleared $R\overline{W}$ bit is received. In slave receiver mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold SCL low if intervention of the CPU is required after a byte has been received.

If the slave should receive data from the master the USCI module is automatically configured as a receiver and UCTR is cleared. After the first data byte is received the receive interrupt flag UCBxRXIFG is set. The USCI module automatically acknowledges the received data and can receive the next data byte.

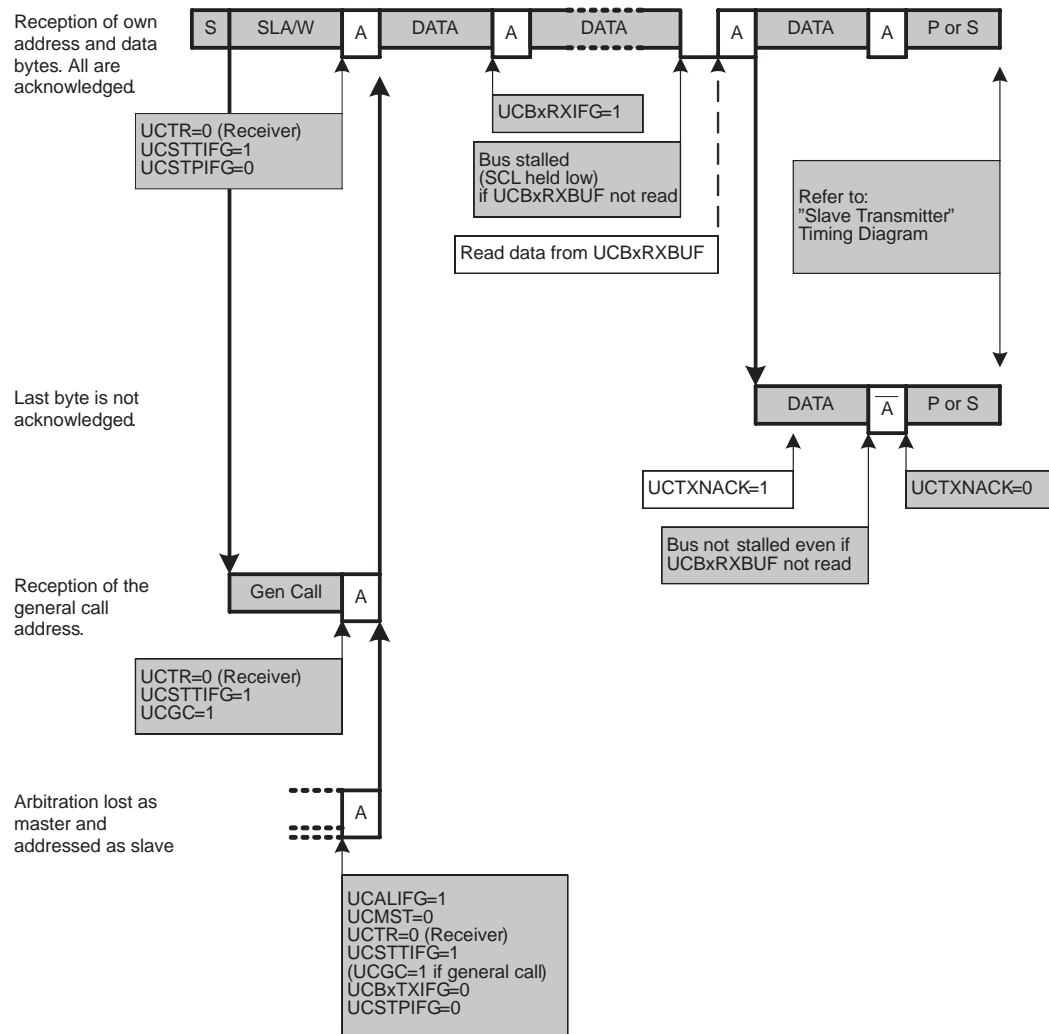

If the previous data wasn't read from the receive buffer UCBxRXBUF at the end of a reception, the bus is stalled by holding SCL low. As soon as UCBxRXBUF is read the new data is transferred into UCBxRXBUF, an acknowledge is sent to the master, and the next data can be received.

Setting the UCTXNACK bit causes a NACK to be transmitted to the master during the next acknowledgment cycle. A NACK is sent even if UCBxRXBUF is not ready to receive the latest data. If the UCTXNACK bit is set while SCL is held low the bus will be released, a NACK is transmitted immediately, and UCBxRXBUF is loaded with the last received data. Since the previous data was not read that data will be lost. To avoid loss of data the UCBxRXBUF needs to be read before UCTXNACK is set.

When the master generates a STOP condition the UCSTPIFG flag is set.

If the master generates a repeated START condition the USCI I2C state machine returns to its address reception state.

Figure 14–10 illustrates the I2C slave receiver operation.

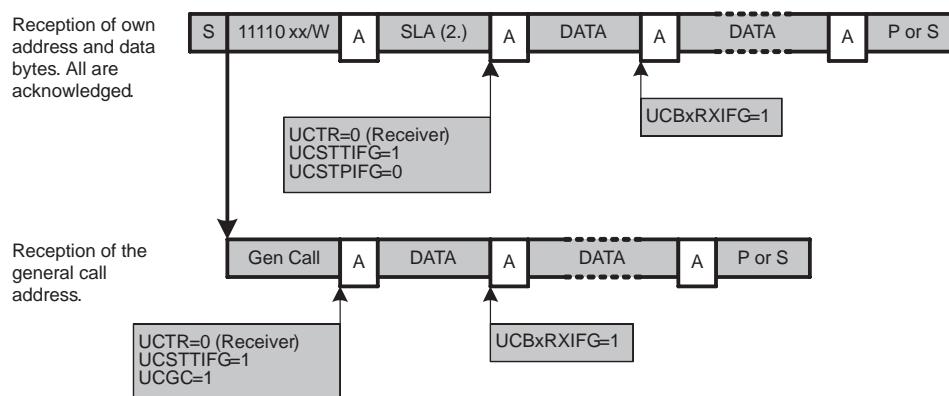

Figure 14–10. I²C Slave Receiver Mode

I2C Slave 10-bit Addressing Mode

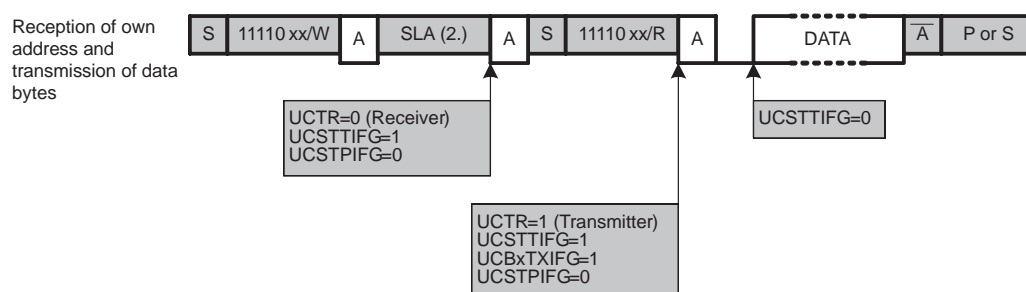

The 10-bit addressing mode is selected when $UCA10 = 1$ and is as shown in Figure 14–11. In 10-bit addressing mode, the slave is in receive mode after the full address is received. The USCI module indicates this by setting the UCSTTIFG flag while the UCTR bit is cleared. To switch the slave into transmitter mode the master sends a repeated START condition together with the first byte of the address but with the R/W bit set. This will set the UCSTTIFG flag if it was previously cleared by software and the USCI module switches to transmitter mode with $UCTR = 1$.

Figure 14–11. I2C Slave 10-bit Addressing Mode

Slave Receiver

Slave Transmitter

Master Mode

The USCI module is configured as an I²C master by selecting the I²C mode with UCMODEx = 11 and UCSYNC = 1 and setting the UCMST bit. When the master is part of a multi-master system, UCMM must be set and its own address must be programmed into the UCBxI2COA register. When UCA10 = 0, 7-bit addressing is selected. When UCA10 = 1, 10-bit addressing is selected. The UCGCEN bit selects if the USCI module responds to a general call.

I²C Master Transmitter Mode

After initialization, master transmitter mode is initiated by writing the desired slave address to the UCBxI2CSA register, selecting the size of the slave address with the UCSLA10 bit, setting UCTR for transmitter mode, and setting UCTXSTT to generate a START condition.

The USCI module checks if the bus is available, generates the START condition, and transmits the slave address. The UCBxTXIFG bit is set when the START condition is generated and the first data to be transmitted can be written into UCBxTXBUF. As soon as the slave acknowledges the address the UCTXSTT bit is cleared.

The data written into UCBxTXBUF is transmitted if arbitration is not lost during transmission of the slave address. UCBxTXIFG is set again as soon as the data is transferred from the buffer into the shift register. If there is no data loaded to UCBxTXBUF before the acknowledge cycle, the bus is held during the acknowledge cycle with SCL low until data is written into UCBxTXBUF. Data is transmitted or the bus is held as long as the UCTXSTP bit or UCTXSTT bit is not set.

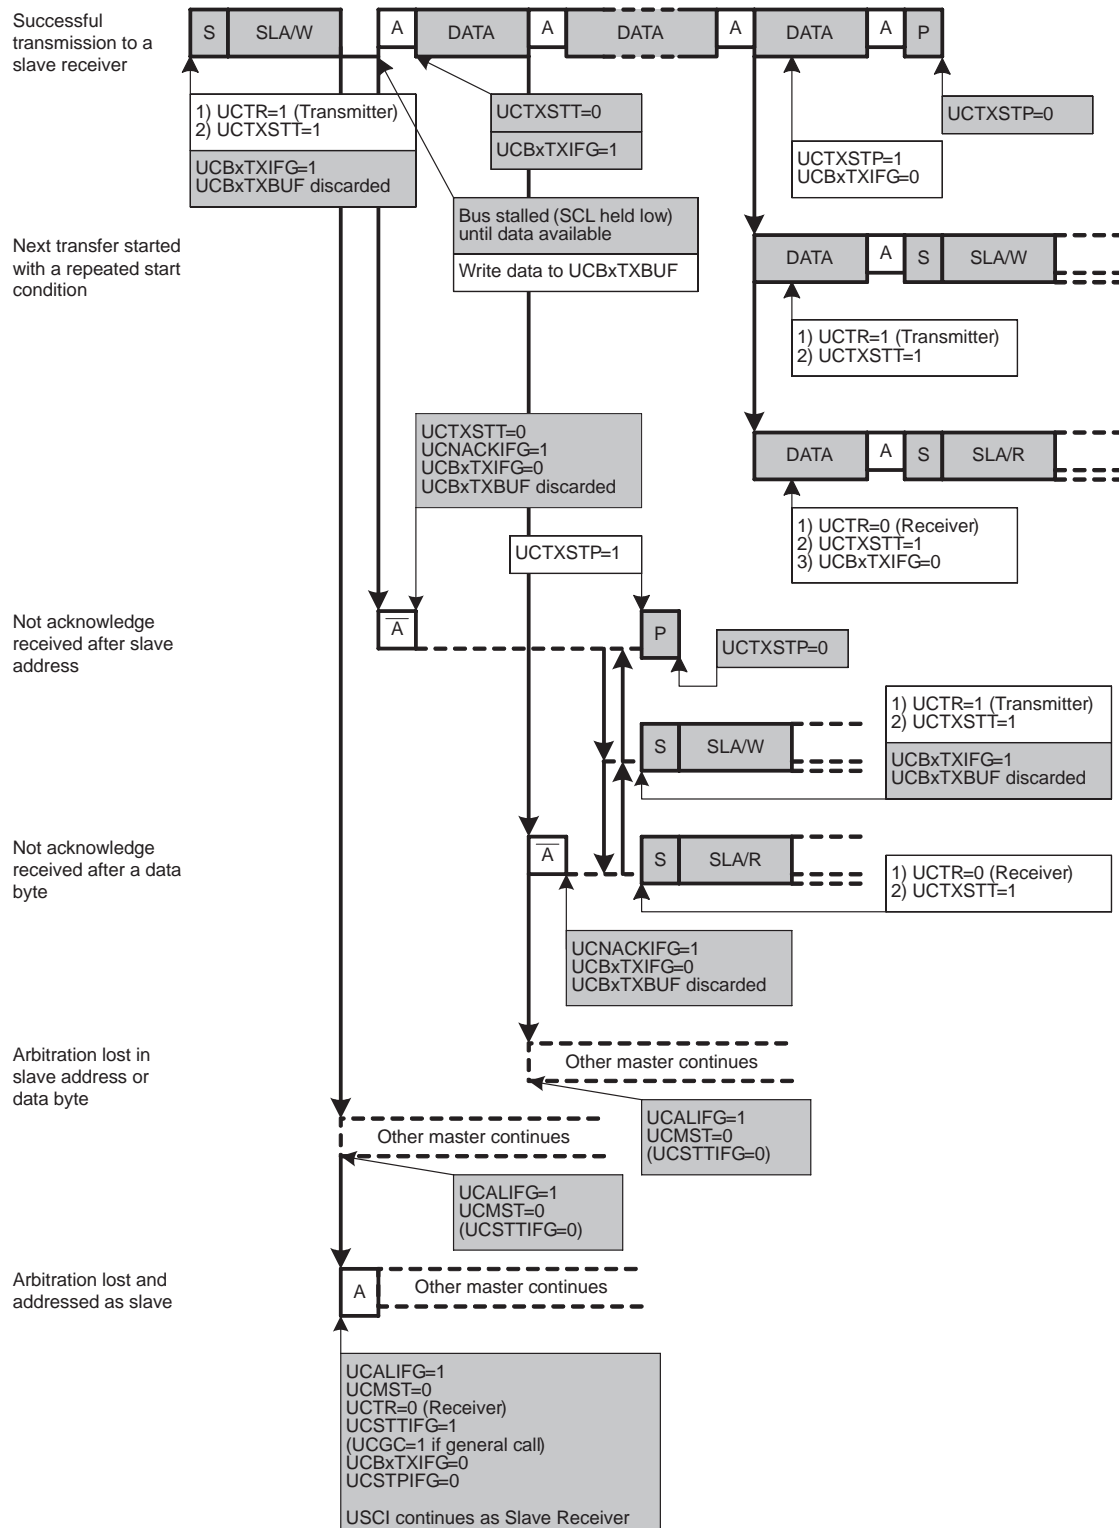

Setting UCTXSTP will generate a STOP condition after the next acknowledge from the slave. If UCTXSTP is set during the transmission of the slave's address or while the USCI module waits for data to be written into UCBxTXBUF, a STOP condition is generated even if no data was transmitted to the slave. When transmitting a single byte of data, the UCTXSTP bit must be set while the byte is being transmitted, or anytime after transmission begins, without writing new data into UCBxTXBUF. Otherwise, only the address will be transmitted. When the data is transferred from the buffer to the shift register, UCBxTXIFG will become set indicating data transmission has begun and the UCTXSTP bit may be set.

Setting UCTXSTT will generate a repeated START condition. In this case, UCTR may be set or cleared to configure transmitter or receiver, and a different slave address may be written into UCBxI2CSA if desired.

If the slave does not acknowledge the transmitted data the not-acknowledge interrupt flag UCNACKIFG is set. The master must react with either a STOP condition or a repeated START condition. If data was already written into UCBxTXBUF it will be discarded. If this data should be transmitted after a repeated START it must be written into UCBxTXBUF again.

Figure 14–12 illustrates the I2C master transmitter operation.

Figure 14–12. I2C Master Transmitter Mode

I²C Master Receiver Mode

After initialization, master receiver mode is initiated by writing the desired slave address to the UCBxI2CSA register, selecting the size of the slave address with the UCSLA10 bit, clearing UCTR for receiver mode, and setting UCTXSTT to generate a START condition.

The USCI module checks if the bus is available, generates the START condition, and transmits the slave address. As soon as the slave acknowledges the address the UCTXSTT bit is cleared.

After the acknowledge of the address from the slave the first data byte from the slave is received and acknowledged and the UCBxRXIFG flag is set. Data is received from the slave as long as UCTXSTP or UCTXSTT is not set. If UCBxRXBUF is not read the master holds the bus during reception of the last data bit and until the UCBxRXBUF is read.

If the slave does not acknowledge the transmitted address the not-acknowledge interrupt flag UCNACKIFG is set. The master must react with either a STOP condition or a repeated START condition.

Setting the UCTXSTP bit will generate a STOP condition. After setting UCTXSTP, a NACK followed by a STOP condition is generated after reception of the data from the slave, or immediately if the USCI module is currently waiting for UCBxRXBUF to be read.

If a master wants to receive a single byte only, the UCTXSTP bit must be set while the byte is being received. For this case, the UCTXSTT may be polled to determine when it is cleared:

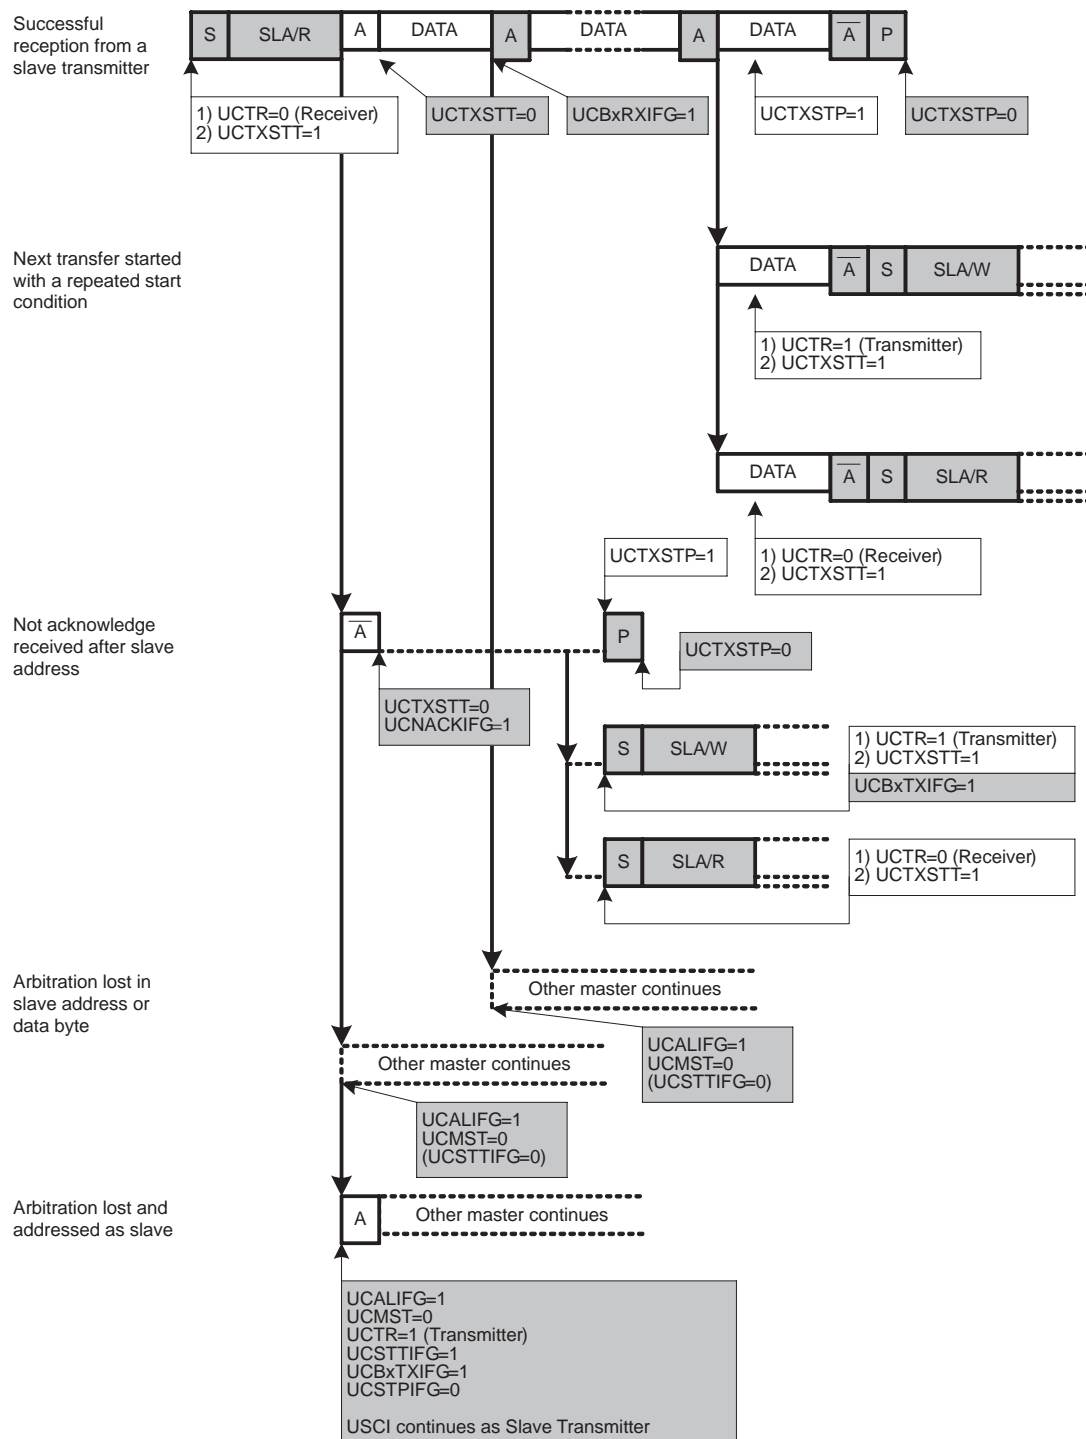

```

        BIS.B #UCTXSTT,&UCB0CTL1 ;Transmit START cond.
POLL_STT BIT.B #UCTXSTT,&UCB0CTL1 ;Poll UCTXSTT bit
        JC     POLL_STT           ;When cleared,
        BIS.B #UCTXSTP,&UCB0CTL1 ;transmit STOP cond.

```

Setting UCTXSTT will generate a repeated START condition. In this case, UCTR may be set or cleared to configure transmitter or receiver, and a different slave address may be written into UCBxI2CSA if desired.

Figure 14–13 illustrates the I²C master receiver operation.

Figure 14–13. I²C Master Receiver Mode

I²C Master 10-bit Addressing Mode

The 10-bit addressing mode is selected when UCSLA10 = 1 and is shown in Figure 14–14.

Figure 14–14. I²C Master 10-bit Addressing Mode

Master Transmitter

Successful transmission to a slave receiver

Master Receiver

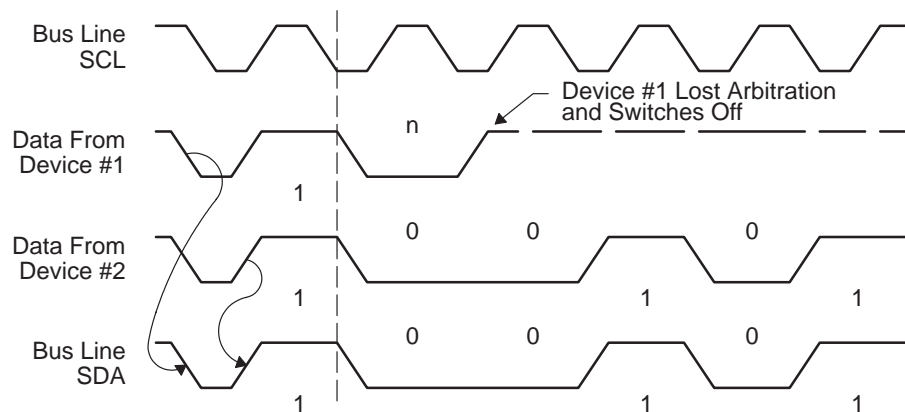

Successful reception from a slave transmitter

Arbitration

If two or more master transmitters simultaneously start a transmission on the bus, an arbitration procedure is invoked. Figure 14–15 illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on SDA by the competing transmitters. The first master transmitter that generates a logic high is overruled by the opposing master generating a logic low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that lost arbitration switches to the slave receiver mode, and sets the arbitration lost flag UCALIFG. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 14–15. Arbitration Procedure Between Two Master Transmitters

If the arbitration procedure is in progress when a repeated START condition or STOP condition is transmitted on SDA, the master transmitters involved in arbitration must send the repeated START condition or STOP condition at the same position in the format frame. Arbitration is not allowed between:

- ☐ A repeated START condition and a data bit
- ☐ A STOP condition and a data bit
- ☐ A repeated START condition and a STOP condition

14.3.5 I²C Clock Generation and Synchronization

The I²C clock SCL is provided by the master on the I²C bus. When the USCI is in master mode, BITCLK is provided by the USCI bit clock generator and the clock source is selected with the UCSSELx bits. In slave mode the bit clock generator is not used and the UCSSELx bits are don't care.

The 16-bit value of UCBRx in registers UCBxBR1 and UCBxBR0 is the division factor of the USCI clock source, BRCLK. The maximum bit clock that can be used in single master mode is $f_{BRCLK}/4$. In multi-master mode the maximum bit clock is $f_{BRCLK}/8$. The BITCLK frequency is given by:

$$f_{\text{BitClock}} = \frac{f_{\text{BRCLK}}}{\text{UCBRx}}$$

The minimum high and low periods of the generated SCL are

$$t_{\text{LOW,MIN}} = t_{\text{HIGH,MIN}} = \frac{\text{UCBRx}/2}{f_{\text{BRCLK}}} \quad \text{when UCBRx is even and}$$

$$t_{\text{LOW,MIN}} = t_{\text{HIGH,MIN}} = \frac{\text{UCBRx}/2}{f_{\text{BRCLK}}} \quad \text{when UCBRx is odd.}$$

The USCI clock source frequency and the prescaler setting UCBRx must to be chosen such that the minimum low and high period times of the I²C specification are met.

During the arbitration procedure the clocks from the different masters must be synchronized. A device that first generates a low period on SCL overrides the other devices forcing them to start their own low periods. SCL is then held low by the device with the longest low period. The other devices must wait for SCL to be released before starting their high periods. Figure 14–16 illustrates the clock synchronization. This allows a slow slave to slow down a fast master.

Figure 14–16. Synchronization of Two I²C Clock Generators During Arbitration

14.3.6 Using the USCI Module in I²C Mode with Low Power Modes

The USCI module provides automatic clock activation for SMCLK for use with low-power modes. When SMCLK is the USCI clock source, and is inactive because the device is in a low-power mode, the USCI module automatically activates it when needed, regardless of the control-bit settings for the clock source. The clock remains active until the USCI module returns to its idle condition. After the USCI module returns to the idle condition, control of the clock source reverts to the settings of its control bits. Automatic clock activation is not provided for ACLK.

When the USCI module activates an inactive clock source, the clock source becomes active for the whole device and any peripheral configured to use the clock source may be affected. For example, a timer using SMCLK will increment while the USCI module forces SMCLK active.

In I²C slave mode no internal clock source is required because the clock is provided by the external master. It is possible to operate the USCI in I²C slave mode while the device is in LPM4 and all internal clock sources are disabled. The receive or transmit interrupts can wake up the CPU from any low power mode.

14.3.7 USCI Interrupts in I²C Mode

There are two interrupt vectors for the USCI module in I²C mode. One interrupt vector is associated with the transmit and receive interrupt flags. The other interrupt vector is associated with the four state change interrupt flags. Each interrupt flag has its own interrupt enable bit. When an interrupt is enabled, and the GIE bit is set, the interrupt flag will generate an interrupt request. DMA transfers are controlled by the UCBxTXIFG and UCBxRXIFG flags on devices with a DMA controller.

I²C Transmit Interrupt Operation

The UCBxTXIFG interrupt flag is set by the transmitter to indicate that UCBxTXBUF is ready to accept another character. An interrupt request is generated if UCBxTXIE and GIE are also set. UCBxTXIFG is automatically reset if a character is written to UCBxTXBUF or if a NACK is received. UCBxTXIFG is set when UCSWRST = 1 and the I²C mode is selected. UCBxTXIE is reset after a PUC or when UCSWRST = 1.

I²C Receive Interrupt Operation

The UCBxRXIFG interrupt flag is set when a character is received and loaded into UCBxRXBUF. An interrupt request is generated if UCBxRXIE and GIE are also set. UCBxRXIFG and UCBxRXIE are reset after a PUC signal or when UCSWRST = 1. UCBxRXIFG is automatically reset when UCBxRXBUF is read.

I²C State Change Interrupt Operation

Table 14–1 Describes the I²C state change interrupt flags.

Table 14–1. I²C State Change Interrupt Flags

Interrupt Flag	Interrupt Condition
UCALIFG	Arbitration-lost. Arbitration can be lost when two or more transmitters start a transmission simultaneously, or when the USCI operates as master but is addressed as a slave by another master in the system. The UCALIFG flag is set when arbitration is lost. When UCALIFG is set the UCMST bit is cleared and the I ² C controller becomes a slave.
UCNACKIFG	Not-acknowledge interrupt. This flag is set when an acknowledge is expected but is not received. UCNACKIFG is automatically cleared when a START condition is received.
UCSTTIFG	Start condition detected interrupt. This flag is set when the I ² C module detects a START condition together with its own address while in slave mode. UCSTTIFG is used in slave mode only and is automatically cleared when a STOP condition is received.
UCSTPIFG	Stop condition detected interrupt. This flag is set when the I ² C module detects a STOP condition while in slave mode. UCSTPIFG is used in slave mode only and is automatically cleared when a START condition is received.

Interrupt Vector Assignment

USCI_Ax and USCI_Bx share the same interrupt vectors. In I²C mode the state change interrupt flags UCSTTIFG, UCSTPIFG, UCIFG, UCALIFG from USCI_Bx and UCAxRXIFG from USCI_Ax are routed to one interrupt vector. The I²C transmit and receive interrupt flags UCBxTXIFG and UCBxRXIFG from USCI_Bx and UCAxTXIFG from USCI_Ax share another interrupt vector.

Shared Interrupt Vectors Software Example

The following software example shows an extract of the interrupt service routine to handle data receive interrupts from USCI_A0 in either UART or SPI mode and state change interrupts from USCI_B0 in I²C mode.

```
USCIA0_RX_USCIB0_I2C_STATE_ISR

14.4 USCI Registers: I2C Mode

The USCI registers applicable in I2C mode for USCI_B0 are listed in Table 14–2 and for USCI_B1 in Table 14–3.

Table 14–2. USCI_B0 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_B0 control register 0	UCB0CTL0	Read/write	068h	001h with PUC
USCI_B0 control register 1	UCB0CTL1	Read/write	069h	001h with PUC
USCI_B0 Bit rate control register 0	UCB0BR0	Read/write	06Ah	Reset with PUC
USCI_B0 Bit rate control register 1	UCB0BR1	Read/write	06Bh	Reset with PUC
USCI_B0 I2C Interrupt enable register	UCB0I2CIE	Read/write	06Ch	Reset with PUC
USCI_B0 status register	UCB0STAT	Read/write	06Dh	Reset with PUC
USCI_B0 Receive buffer register	UCB0RXBUF	Read	06Eh	Reset with PUC
USCI_B0 Transmit buffer register	UCB0TXBUF	Read/write	06Fh	Reset with PUC
USCI_B0 I2C Own Address register	UCB0I2COA	Read/write	0118h	Reset with PUC
USCI_B0 I2C Slave Address register	UCB0I2CSA	Read/write	011Ah	Reset with PUC
SFR interrupt enable register 2	IE2	Read/write	001h	Reset with PUC
SFR interrupt flag register 2	IFG2	Read/write	003h	00Ah with PUC

Note: Modifying SFR bits

To avoid modifying control bits of other modules, it is recommended to set or clear the IEx and IFGx bits using `BIS.B` or `BIC.B` instructions, rather than `MOV.B` or `CLR.B` instructions.

Table 14–3. USCI_B1 Control and Status Registers

Register	Short Form	Register Type	Address	Initial State
USCI_B1 control register 0	UCB1CTL0	Read/write	0D8h	Reset with PUC
USCI_B1 control register 1	UCB1CTL1	Read/write	0D9h	001h with PUC
USCI_B1 Baud rate control register 0	UCB1BR0	Read/write	0DAh	Reset with PUC
USCI_B1 Baud rate control register 1	UCB1BR1	Read/write	0DBh	Reset with PUC
USCI_B1 I2C Interrupt enable register	UCB1I2CIE	Read/write	0DCh	Reset with PUC
USCI_B1 status register	UCB1STAT	Read/write	0DDh	Reset with PUC
USCI_B1 Receive buffer register	UCB1RXBUF	Read	0DEh	Reset with PUC
USCI_B1 Transmit buffer register	UCB1TXBUF	Read/write	0DFh	Reset with PUC
USCI_B1 I2C Own Address register	UCB1I2COA	Read/write	017Ch	Reset with PUC
USCI_B1 I2C Slave Address register	UCB1I2CSA	Read/write	017Eh	Reset with PUC
USCI_A1/B1 interrupt enable register	UC1IE	Read/write	006h	Reset with PUC
USCI_A1/B1 interrupt flag register	UC1IFG	Read/write	007h	00Ah with PUC

UCBxCTL0, USCI_Bx Control Register 0

7	6	5	4	3	2	1	0
UCA10	UCSLA10	UCMM	Unused	UCMST	UCMODEx=11		UCSYNC=1
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	r-1

UCA10	Bit 7	Own addressing mode select 0 Own address is a 7-bit address 1 Own address is a 10-bit address
UCSLA10	Bit 6	Slave addressing mode select 0 Address slave with 7-bit address 1 Address slave with 10-bit address
UCMM	Bit 5	Multi-master environment select 0 Single master environment. There is no other master in the system. The address compare unit is disabled. 1 Multi master environment
Unused	Bit 4	Unused
UCMST	Bit 3	Master mode select. When a master loses arbitration in a multi-master environment (UCMM = 1) the UCMST bit is automatically cleared and the module acts as slave. 0 Slave mode 1 Master mode
UCMODEx	Bits 2-1	USCI Mode. The UCMODEx bits select the synchronous mode when UCSYNC = 1. 00 3-Pin SPI 01 4-Pin SPI (master/slave enabled if STE = 1) 10 4-Pin SPI (master/slave enabled if STE = 0) 11 I ² C Mode
UCSYNC	Bit 0	Synchronous mode enable 0 Asynchronous mode 1 Synchronous Mode

UCBxCTL1, USCI_Bx Control Register 1

7	6	5	4	3	2	1	0
UCSSELx		Unused	UCTR	UCTXNACK	UCTXSTP	UCTXSTT	UCSWRST
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-1

UCSSELx	Bits	USCI clock source select. These bits select the BRCLK source clock.	
	7-6	00	UCLKI
		01	ACLK
		10	SMCLK
		11	SMCLK
Unused	Bit 5	Unused	
UCTR	Bit 4	Transmitter/Receiver	
		0	Receiver
		1	Transmitter
UCTXNACK	Bit 3	Transmit a NACK. UCTXNACK is automatically cleared after a NACK is transmitted.	
		0	Acknowledge normally
		1	Generate NACK
UCTXSTP	Bit 2	Transmit STOP condition in master mode. Ignored in slave mode. In master receiver mode the STOP condition is preceded by a NACK. UCTXSTP is automatically cleared after STOP is generated.	
		0	No STOP generated
		1	Generate STOP
UCTXSTT	Bit 1	Transmit START condition in master mode. Ignored in slave mode. In master receiver mode a repeated START condition is preceded by a NACK. UCTXSTT is automatically cleared after START condition and address information is transmitted.	
		Ignored in slave mode.	
		0	Do not generate START condition
		1	Generate START condition
UCSWRST	Bit 0	Software reset enable	
		0	Disabled. USCI reset released for operation.
		1	Enabled. USCI logic held in reset state.

UCBxBR0, USCI_Bx Baud Rate Control Register 0

UCBxBR1, USCI_Bx Baud Rate Control Register 1

UCBRx Bit clock prescaler. The 16-bit value of {UCxxBR0+UCxxBR1} form the prescaler value.

UCBxSTAT, USCI_Bx Status Register

7	6	5	4	3	2	1	0
Unused	UC SCLLOW	UCGC	UCBBUSY	UCNACK IFG	UCSTPIFG	UCSTTIFG	UCALIFG
rw-0	r-0	rw-0	r-0	rw-0	rw-0	rw-0	rw-0

Unused	Bit 7	Unused.
UC SCLLOW	Bit 6	SCL low 0 SCL is not held low 1 SCL is held low
UCGC	Bit 5	General call address received. UCGC is automatically cleared when a START condition is received. 0 No general call address received 1 General call address received
UCBBUSY	Bit 4	Bus busy 0 Bus inactive 1 Bus busy
UCNACK IFG	Bit 3	Not-acknowledge received interrupt flag. UCNACKIFG is automatically cleared when a START condition is received. 0 No interrupt pending 1 Interrupt pending
UCSTPIFG	Bit 2	Stop condition interrupt flag. UCSTPIFG is automatically cleared when a START condition is received. 0 No interrupt pending 1 Interrupt pending
UCSTTIFG	Bit 1	Start condition interrupt flag. UCSTTIFG is automatically cleared if a STOP condition is received. 0 No interrupt pending 1 Interrupt pending
UCALIFG	Bit 0	Arbitration lost interrupt flag 0 No interrupt pending 1 Interrupt pending

UCBxRXBUF, USCI_Bx Receive Buffer Register

UCRXBUFx Bits 7–0 The receive-data buffer is user accessible and contains the last received character from the receive shift register. Reading UCBxRXBUF resets UCBxRXIFG.

UCBxTXBUF, USCI_Bx Transmit Buffer Register

UCTXBUFx Bits 7–0 The transmit data buffer is user accessible and holds the data waiting to be moved into the transmit shift register and transmitted. Writing to the transmit data buffer clears UCBxTXIFG.

UCBxI2COA, USCIBx I²C Own Address Register

- UCGCEN** Bit 15 General call response enable
 0 Do not respond to a general call
 1 Respond to a general call
- I2COAx** Bits I²C own address. The I2COAx bits contain the local address of the USCI_Bx I²C controller. The address is right-justified. In 7-bit addressing mode Bit 6 is the MSB, Bits 9-7 are ignored. In 10-bit addressing mode Bit 9 is the MSB.

UCBxI2CSA, USCI_Bx I²C Slave Address Register

- I2CSAx** Bits I²C slave address. The I2CSAx bits contain the slave address of the external device to be addressed by the USCI_Bx module. It is only used in master mode. The address is right-justified. In 7-bit slave addressing mode Bit 6 is the MSB, Bits 9-7 are ignored. In 10-bit slave addressing mode Bit 9 is the MSB.

UCBxI2CIE, USCI_Bx I2C Interrupt Enable Register

Reserved	Bits 7-4	Reserved
UCNACKIE	Bit 3	Not-acknowledge interrupt enable 0 Interrupt disabled 1 Interrupt enabled
UCSTPIE	Bit 2	Stop condition interrupt enable 0 Interrupt disabled 1 Interrupt enabled
UCSTTIE	Bit 1	Start condition interrupt enable 0 Interrupt disabled 1 Interrupt enabled
UCALIE	Bit 0	Arbitration lost interrupt enable 0 Interrupt disabled 1 Interrupt enabled

IE2, Interrupt Enable Register 2

7	6	5	4	3	2	1	0
				UCB0TXIE	UCB0RXIE		
				rw-0	rw-0		

Bits 7-4 These bits may be used by other modules. See device-specific datasheet.

UCB0TXIE Bit 3 USCI_B0 transmit interrupt enable
 0 Interrupt disabled
 1 Interrupt enabled

UCB0RXIE Bit 2 USCI_B0 receive interrupt enable
 0 Interrupt disabled
 1 Interrupt enabled

Bits 1-0 These bits may be used by other modules. See device-specific datasheet.

IFG2, Interrupt Flag Register 2

7	6	5	4	3	2	1	0
				UCB0TXIFG	UCB0RXIFG		
				rw-1	rw-0		

Bits 7-4 These bits may be used by other modules. See device-specific datasheet.

UCB0TXIFG Bit 3 USCI_B0 transmit interrupt flag. UCB0TXIFG is set when UCB0TXBUF is empty.
 0 No interrupt pending
 1 Interrupt pending

UCB0RXIFG Bit 2 USCI_B0 receive interrupt flag. UCB0RXIFG is set when UCB0RXBUF has received a complete character.
 0 No interrupt pending
 1 Interrupt pending

Bits 1-0 These bits may be used by other modules. See device-specific datasheet.

UC1IE, USCI_B1 Interrupt Enable Register

7	6	5	4	3	2	1	0
Unused	Unused	Unused	Unused	UCB1TXIE	UCB1RXIE		
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0		

Unused Bits Unused
7-4

UCB1TXIE Bit 3 USCI_B1 transmit interrupt enable
0 Interrupt disabled
1 Interrupt enabled

UCB1RXIE Bit 2 USCI_B1 receive interrupt enable
0 Interrupt disabled
1 Interrupt enabled

Bits These bits may be used by other USCI modules. See device-specific
1-0 datasheet.

UC1IFG, USCI_B1 Interrupt Flag Register

7	6	5	4	3	2	1	0
Unused	Unused	Unused	Unused	UCB1TXIFG	UCB1RXIFG		
rw-0	rw-0	rw-0	rw-0	rw-1	rw-0		

Unused Bits Unused.
7-4

UCB1TXIFG Bit 3 USCI_B1 transmit interrupt flag. UCB1TXIFG is set when UCB1TXBUF is empty.
0 No interrupt pending
1 Interrupt pending

UCB1RXIFG Bit 2 USCI_B1 receive interrupt flag. UCB1RXIFG is set when UCB1RXBUF has received a complete character.
0 No interrupt pending
1 Interrupt pending

Bits These bits may be used by other modules. See device-specific
1-0 datasheet.

OA

The OA is a general purpose operational amplifier. This chapter describes the OA. Two OA modules are implemented in the MSP430x22x4 devices.

Topic	Page
15.1 OA Introduction	15-2
15.2 OA Operation	15-4
15.3 OA Registers	15-12

15.1 OA Introduction

The OA op amps support front-end analog signal conditioning prior to analog-to-digital conversion.

Features of the OA include:

- ☐ Single supply, low-current operation
- ☐ Rail-to-rail output
- ☐ Programmable settling time vs. power consumption
- ☐ Software selectable configurations
- ☐ Software selectable feedback resistor ladder for PGA implementations

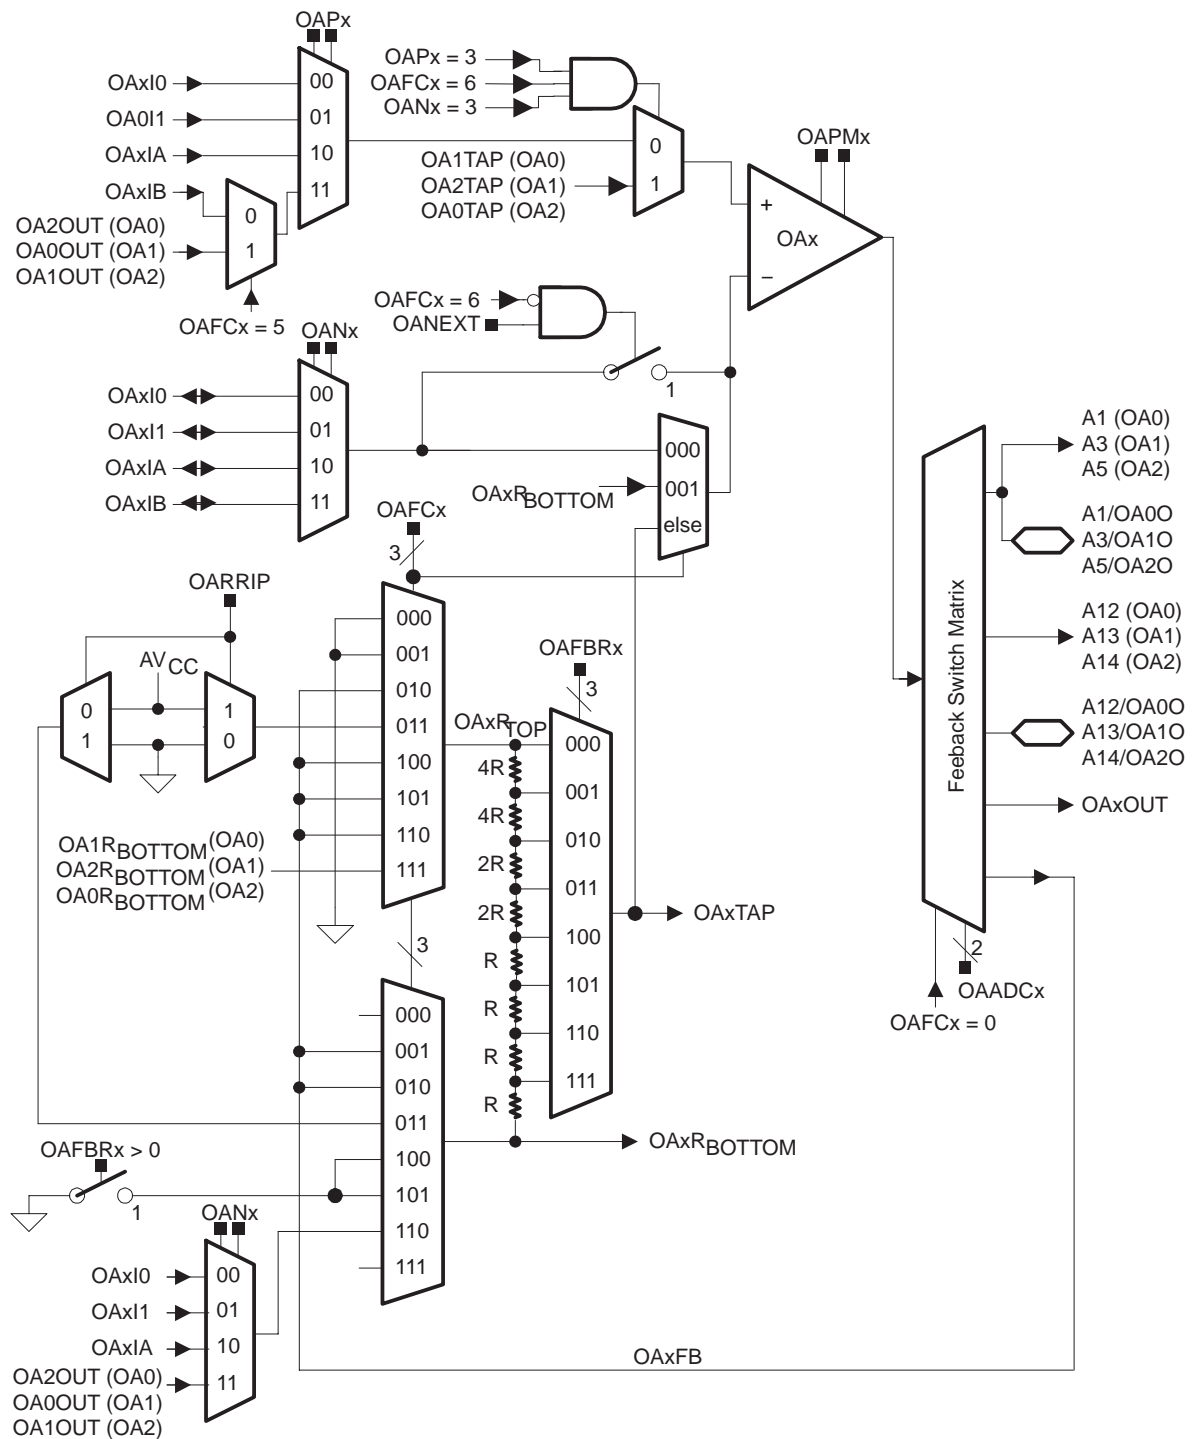

Note: Multiple OA Modules

Some devices may integrate more than one OA module. In the case where more than one OA is present on a device, the multiple OA modules operate identically.

Throughout this chapter, nomenclature appears such as OAxCTL0 to describe register names. When this occurs, the x is used to indicate which OA module is being discussed. In cases where operation is identical, the register is simply referred to as OAxCTL0.

The block diagram of the OA module is shown in Figure 15–1.

Figure 15–1. OA Block Diagram

15.2 OA Operation

The OA module is configured with user software. The setup and operation of the OA is discussed in the following sections.

15.2.1 OA Amplifier

The OA is a configurable, low-current, rail-to-rail output operational amplifier. It can be configured as an inverting amplifier, or a non-inverting amplifier, or can be combined with other OA modules to form differential amplifiers. The output slew rate of the OA can be configured for optimized settling time vs. power consumption with the OAPMx bits. When OAPMx = 00 the OA is off and the output is high-impedance. When OAPMx > 0, the OA is on. See the device-specific datasheet for parameters.

15.2.2 OA Input

The OA has configurable input selection. The signals for the + and – inputs are individually selected with the OANx and OAPx bits and can be selected as external signals or internal signals. OAxI0 and OAxI1 are external signals provided for each OA module. OA0I1 provides a non-inverting input that is tied together internally for all OA modules. OAxIA and OAxIB provide device-dependent inputs. Refer to the device datasheet for signal connections.

When the external inverting input is not needed for a mode, setting the OANEXT bit makes the internal inverting input externally available.

15.2.3 OA Output and Feedback Routing

The OA has configurable output selection controlled by the OAADCx bits and the OAFCx bits. The OA output signals can be routed to ADC12 inputs A12 (OA0), A13 (OA1), or A14 (OA2) internally, or can be routed to these ADC inputs and their external pins. The OA output signals can also be routed to ADC inputs A1 (OA0), A3 (OA1), or A5 (OA2) and the corresponding external pin. The OA output is also connected to an internal R-ladder with the OAFCx bits. The R-ladder tap is selected with the OAFBRx bits to provide programmable gain amplifier functionality.

Table 15–1 shows the OA output and feedback routing configurations. When OAFCx = 0 the OA is in general-purpose mode and feedback is achieved externally to the device. When OAFCx > 0 and when OAADCx = 00 or 11, the output of the OA is kept internal to the device. When OAFCx > 0 and OAADCx = 01 or 10, the OA output is routed both internally and externally.

Table 15–1. OA Output Configurations

OAFCx	OAADCx	OA Output and Feedback Routing
= 0	x0	OAxOUT connected to external pins and ADC input A1, A3, or A5.
= 0	x1	OAxOUT connected to external pins and ADC input A12, A13, or A14.
> 0	00	OAxOUT used for internal routing only.
> 0	01	OAxOUT connected to external pins and ADC input A12, A13, or A14.
> 0	10	OAxOUT connected to external pins and ADC input A1, A3, or A5.
> 0	11	OAxOUT connected internally to ADC input A12, A13, or A14. External A12, A13, or A14 pin connections are disconnected from the ADC.

15.2.4 OA Configurations

The OA can be configured for different amplifier functions with the OAFx bits as listed in Table 15–2.

Table 15–2. OA Mode Select

OAFx	OA Mode
000	General-purpose opamp
001	Unity gain buffer for three-opamp differential amplifier
010	Unity gain buffer
011	Comparator
100	Non-inverting PGA amplifier
101	Cascaded non-inverting PGA amplifier
110	Inverting PGA amplifier
111	Differential amplifier

General Purpose Opamp Mode

In this mode the feedback resistor ladder is isolated from the OAx and the OAxCTL0 bits define the signal routing. The OAx inputs are selected with the OAPx and OANx bits. The OAx output is connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Unity Gain Mode for Differential Amplifier

In this mode the output of the OAx is connected to the inverting input of the OAx providing a unity gain buffer. The non-inverting input is selected by the OAPx bits. The external connection for the inverting input is disabled and the OANx bits are don't care. The output of the OAx is also routed through the resistor ladder as part of the three-opamp differential amplifier. This mode is only for construction of the three-opamp differential amplifier.

Unity Gain Mode

In this mode the output of the OAx is connected to the inverting input of the OAx providing a unity gain buffer. The non-inverting input is selected by the OAPx bits. The external connection for the inverting input is disabled and the OANx bits are don't care. The OAx output is connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Comparator Mode

In this mode the output of the OAx is isolated from the resistor ladder. R_{TOP} is connected to AV_{SS} and R_{BOTTOM} is connected to AV_{CC} when $OARRIP = 0$. When $OARRIP = 1$, the connection of the resistor ladder is reversed. R_{TOP} is connected to AV_{CC} and R_{BOTTOM} is connected to AV_{SS} . The OAxTAP signal is connected to the inverting input of the OAx providing a comparator with a programmable threshold voltage selected by the OAFBRx bits. The non-inverting input is selected by the OAPx bits. Hysteresis can be added by an external positive feedback resistor. The external connection for the inverting input is disabled and the OANx bits are don't care. The OAx output is connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Non-Inverting PGA Mode

In this mode the output of the OAx is connected to R_{TOP} and R_{BOTTOM} is connected to AV_{SS} . The OAxTAP signal is connected to the inverting input of the OAx providing a non-inverting amplifier configuration with a programmable gain of $[1 + OAxTAP \text{ ratio}]$. The OAxTAP ratio is selected by the OAFBRx bits. If the OAFBRx bits = 0, the gain is unity. The non-inverting input is selected by the OAPx bits. The external connection for the inverting input is disabled and the OANx bits are don't care. The OAx output is connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Cascaded Non-Inverting PGA Mode

This mode allows internal routing of the OA signals to cascade two or three OA in non-inverting mode. In this mode the non-inverting input of the OAx is connected to OA2OUT (OA0), OA0OUT (OA1), or OA1OUT (OA2) when $OAPx = 11$. The OAx outputs are connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Inverting PGA Mode

In this mode the output of the OAx is connected to R_{TOP} and R_{BOTTOM} is connected to an analog multiplexer that multiplexes the OAxI0, OAxI1, OAxIA, or the output of one of the remaining OAs, selected with the OANx bits. The OAxTAP signal is connected to the inverting input of the OAx providing an inverting amplifier with a gain of $-OAxTAP \text{ ratio}$. The OAxTAP ratio is selected by the OAFBRx bits. The non-inverting input is selected by the OAPx bits. The OAx output is connected to the ADC12 input channel as selected by the OAxCTL0 bits.

Note: Using OAx Negative Input Simultaneously as ADC Input

When the pin connected to the negative input multiplexer is also used as an input to the ADC, conversion errors up to 5mV may be observed due to internal wiring voltage drops.

Differential Amplifier Mode

This mode allows internal routing of the OA signals for a two-opamp or three-opamp instrumentation amplifier. Figure 15–2 shows a two-opamp configuration with OA0 and OA1. In this mode the output of the OA_x is connected to R_{TOP} by routing through another OA_x in the Inverting PGA mode. R_{BOTTOM} is unconnected providing a unity gain buffer. This buffer is combined with one or two remaining OA_x to form the differential amplifier. The OA_x output is connected to the ADC12 input channel as selected by the OA_xCTL0 bits.

Figure 15–2 shows an example of a two-opamp differential amplifier using OA0 and OA1. The control register settings and are shown in Table 15–3. The gain for the amplifier is selected by the OAFBR_x bits for OA1 and is shown in Table 15–4. The OA_x interconnections are shown in Figure 15–3.

Table 15–3. Two-Opamp Differential Amplifier Control Register Settings

Register	Settings (binary)

Figure 15–2. Two Opamp Differential Amplifier

Figure 15–3. Two Opamp Differential Amplifier OAx Interconnections

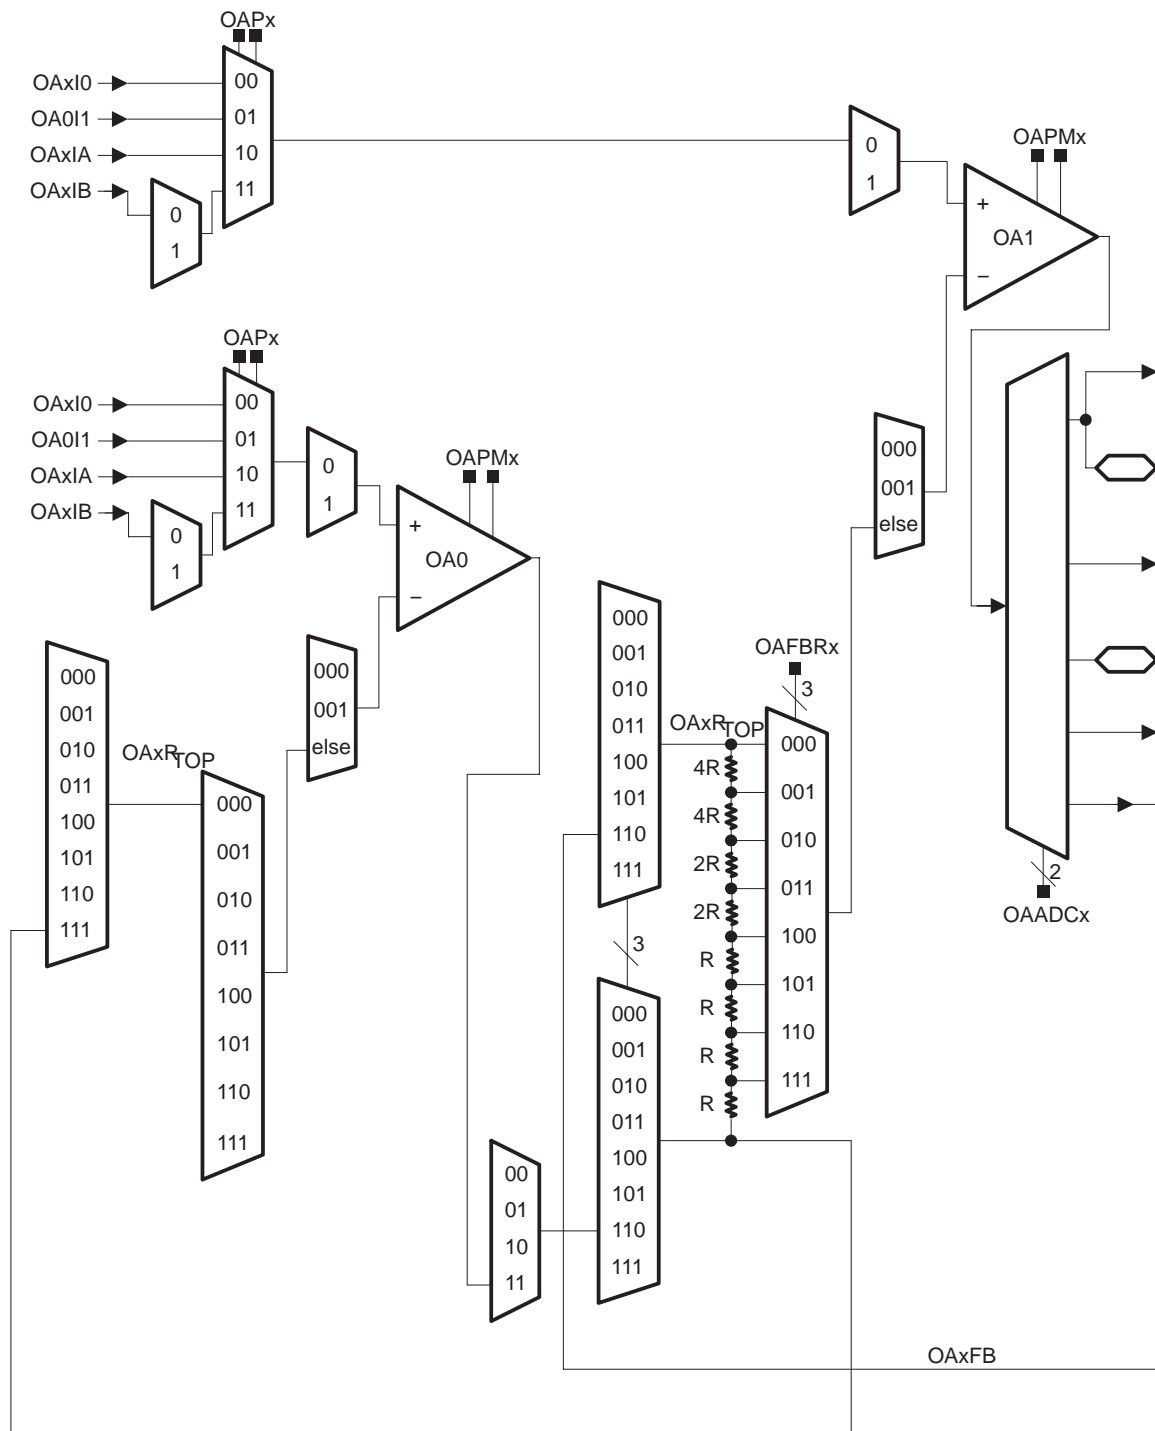

Figure 15–4 shows an example of a three-opamp differential amplifier using OA0, OA1 and OA2 (Three opamps are not available on all devices. See device-specific datasheet for implementation.). The control register settings are shown in Table 15–5. The gain for the amplifier is selected by the OAFBRx bits of OA0 and OA2. The OAFBRx settings for both OA0 and OA2 must be equal. The gain settings are shown in Table 15–6. The OAx interconnections are shown in Figure 15–5.

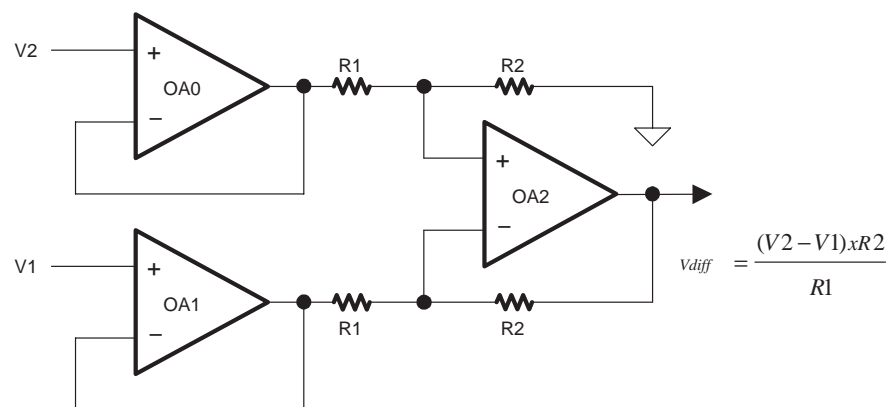

Table 15–5. Three-Opamp Differential Amplifier Control Register Settings

Register	Settings (binary)
OA0CTL0	xx xx xx 0 0

15.3 OA Registers

The OA registers are listed in Table 15–7.

Table 15–7.

Register	Short Form	Register Type	Address	Initial State
OA0 Control Register 0	OA0CTL0	Read/write	0C0h	Reset with POR
OA0 Control Register 1	OA0CTL1	Read/write	0C1h	Reset with POR
OA1 Control Register 0	OA1CTL0	Read/write	0C2h	Reset with POR
OA1 Control Register 1	OA1CTL1	Read/write	0C3h	Reset with POR
OA2 Control Register 0	OA2CTL0	Read/write	0C4h	Reset with POR
OA2 Control Register 1	OA2CTL1	Read/write	0C5h	Reset with POR

OAxCTL0, Opamp Control Register 0

7	6	5	4	3	2	1	0
OANx		OAPx		OAPMx		OAADCx	
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0

OANx	Bits 7-6	Inverting input select. These bits select the input signal for the OA inverting input. 00 OAxI0 01 OAxI1 10 OAxIA – refer to device datasheet for connected signal 11 OAxIB – refer to device datasheet for connected signal
OAPx	Bits 5-4	Non-inverting input select. These bits select the input signal for the OA non-inverting input. 00 OAxI0 01 OAxI1 10 OAxIA – refer to device datasheet for connected signal 11 OAxIB – refer to device datasheet for connected signal
OAPMx	Bits 3-2	Slew rate select. These bits select the slew rate vs. current consumption for the OA. 00 Off, output high Z 01 Slow 10 Medium 11 Fast
OAADCx	Bits 1-0	OA output select. These bits, together with the OAFCx bits, control the routing of the OAx output when OAPMx > 0. When OAFCx = 0: 00 OAxOUT connected to external pins and ADC input A1, A3, or A5 01 OAxOUT connected to external pins and ADC input A12, A13, or A14 10 OAxOUT connected to external pins and ADC input A1, A3, or A5 11 OAxOUT connected to external pins and ADC input A12, A13, or A14 When OAFCx > 0: 00 OAxOUT used for internal routing only 01 OAxOUT connected to external pins and ADC input A12, A13, or A14 10 OAxOUT connected to external pins and ADC input A1, A3, or A5 11 OAxOUT connected internally to ADC input A12, A13, or A14. External A12, A13, or A14 pin connections are disconnected from the ADC.

OAxCTL1, Opamp Control Register 1

OAFBRx	Bits 7-5	OAx feedback resistor select	
		000	Tap 0 – 0R/16R
		001	Tap 1 – 4R/12R
		010	Tap 2 – 8R/8R
		011	Tap 3 – 10R/6R
		100	Tap 4 – 12R/4R
		101	Tap 5 – 13R/3R
		110	Tap 6 – 14R/2R
		111	Tap 7 – 15R/1R
O AFCx	Bits 4-2	OAx function control. This bit selects the function of OAx	
		000	General purpose opamp
		001	Unity gain buffer for three-opamp differential amplifier
		010	Unity gain buffer
		011	Comparator
		100	Non-inverting PGA amplifier
		101	Cascaded non-inverting PGA amplifier
		110	Inverting PGA amplifier
OANEXT	Bit 1	OAx Inverting input externally available. This bit, when set, connects the inverting OAx input to the external pin when the integrated resistor network is used.	
		0	OAx inverting input not externally available
		1	OAx inverting input externally available
OARRIP	Bit 0	OAx reverse resistor connection in comparator mode	
		0	R _{TOP} is connected to AV _{SS} and R _{BOTTOM} is connected to AV _{CC} when O AFCx = 3
		1	R _{TOP} is connected to AV _{CC} and R _{BOTTOM} is connected to AV _{SS} when O AFCx = 3.

Comparator_A+

Comparator_A+ is an analog voltage comparator. This chapter describes Comparator_A+. The Comparator_A+ is implemented in all MSP430x2xx devices except MSP430x20x0 and MSP430x22x4 devices.

16.2 Comparator_A+ Operation	16-4
16.3 Comparator_A+ Registers	16-10

16.1 Comparator_A+ Introduction

The Comparator_A+ module supports precision slope analog-to-digital conversions, supply voltage supervision, and monitoring of external analog signals.

Features of Comparator_A+ include:

- ☐ Inverting and non-inverting terminal input multiplexer
- ☐ Software selectable RC-filter for the comparator output
- ☐ Output provided to Timer_A capture input
- ☐ Software control of the port input buffer
- ☐ Interrupt capability
- ☐ Selectable reference voltage generator
- ☐ Comparator and reference generator can be powered down
- ☐ Input Multiplexer

The Comparator_A+ block diagram is shown in Figure 16–1.

16.2 Comparator_A+ Operation

The Comparator_A+ module is configured with user software. The setup and operation of Comparator_A+ is discussed in the following sections.

16.2.1 Comparator

The comparator compares the analog voltages at the + and – input terminals. If the + terminal is more positive than the – terminal, the comparator output CAOUT is high. The comparator can be switched on or off using control bit CAON. The comparator should be switched off when not in use to reduce current consumption. When the comparator is switched off, the CAOUT is always low.

16.2.2 Input Analog Switches

The analog input switches connect or disconnect the two comparator input terminals to associated port pins using the P2CAx bits. Both comparator terminal inputs can be controlled individually. The P2CAx bits allow:

- ☐ Application of an external signal to the + and – terminals of the comparator
- ☐ Routing of an internal reference voltage to an associated output port pin

Internally, the input switch is constructed as a T-switch to suppress distortion in the signal path.

Note: Comparator Input Connection

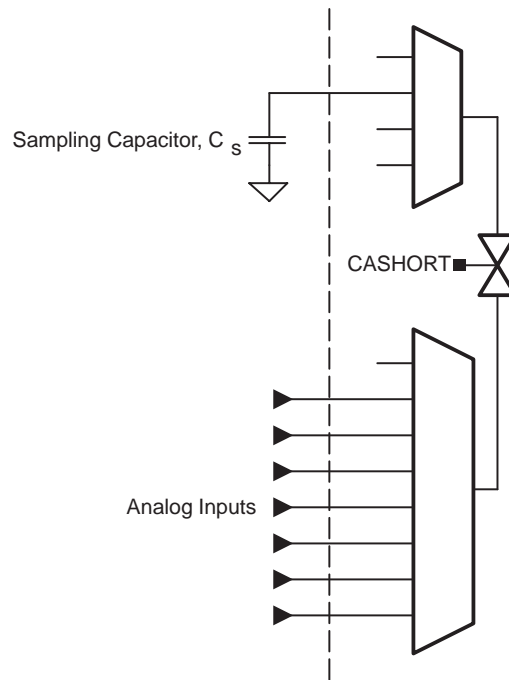

When the comparator is on, the input terminals should be connected to a signal, power, or ground. Otherwise, floating levels may cause unexpected interrupts and increased current consumption.

The CAEX bit controls the input multiplexer, exchanging which input signals are connected to the comparator's + and – terminals. Additionally, when the comparator terminals are exchanged, the output signal from the comparator is inverted. This allows the user to determine or compensate for the comparator input offset voltage.

16.2.3 Input Short Switch

The CASHORT bit shorts the comparator_A+ inputs. This can be used to build a simple sample-and-hold for the comparator as shown in Figure 16–2.

Figure 16–2. Comparator_A+ Sample–And–Hold

The required sampling time is proportional to the size of the sampling capacitor (C_S), the resistance of the input switches in series with the short switch (R_I), and the resistance of the external source (R_S). The total internal resistance (R_I) is typically in the range of 2 – 10 k Ω . The sampling capacitor C_S should be greater than 100pF. The time constant, Tau, to charge the sampling capacitor C_S can be calculated with the following equation:

$$\text{Tau} = (R_I + R_S) \times C_S$$

Depending on the required accuracy 3 to 10 Tau should be used as a sampling time. With 3 Tau the sampling capacitor is charged to approximately 95% of the input signals voltage level, with 5 Tau it is charge to more than 99% and with 10 Tau the sampled voltage is sufficient for 12–bit accuracy.

16.2.4 Output Filter

The output of the comparator can be used with or without internal filtering. When control bit CAF is set, the output is filtered with an on-chip RC-filter.

Any comparator output oscillates if the voltage difference across the input terminals is small. Internal and external parasitic effects and cross coupling on and between signal lines, power supply lines, and other parts of the system are responsible for this behavior as shown in Figure 16–3. The comparator output oscillation reduces accuracy and resolution of the comparison result. Selecting the output filter can reduce errors associated with comparator oscillation.

Figure 16–3. RC-Filter Response at the Output of the Comparator

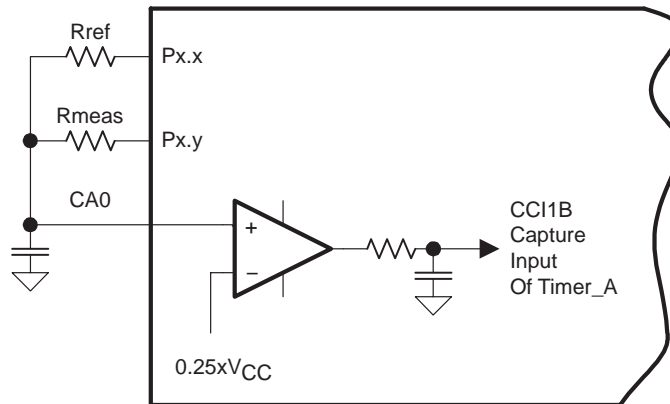

16.2.5 Voltage Reference Generator

The voltage reference generator is used to generate V_{CAREF} , which can be applied to either comparator input terminal. The CAREF_x bits control the output of the voltage generator. The CARSEL bit selects the comparator terminal to which V_{CAREF} is applied. If external signals are applied to both comparator input terminals, the internal reference generator should be turned off to reduce current consumption. The voltage reference generator can generate a fraction of the device's V_{CC} or a fixed transistor threshold voltage of ~ 0.55 V.

16.2.8 Comparator_A+ Used to Measure Resistive Elements

The Comparator_A+ can be optimized to precisely measure resistive elements using single slope analog-to-digital conversion. For example, temperature can be converted into digital data using a thermistor, by comparing the thermistor's capacitor discharge time to that of a reference resistor as shown in Figure 16–6. A reference resistor R_{ref} is compared to R_{meas} .

Figure 16–6. Temperature Measurement System

The MSP430 resources used to calculate the temperature sensed by R_{meas} are:

- ☐ Two digital I/O pins to charge and discharge the capacitor.
- ☐ I/O set to output high (V_{CC}) to charge capacitor, reset to discharge.
- ☐ I/O switched to high-impedance input with CAPDx set when not in use.
- ☐ One output charges and discharges the capacitor via R_{ref} .
- ☐ One output discharges capacitor via R_{meas} .
- ☐ The + terminal is connected to the positive terminal of the capacitor.
- ☐ The – terminal is connected to a reference level, for example $0.25 \times V_{CC}$.
- ☐ The output filter should be used to minimize switching noise.
- ☐ CAOUT used to gate Timer_A CCI1B, capturing capacitor discharge time.

More than one resistive element can be measured. Additional elements are connected to CA0 with available I/O pins and switched to high impedance when not being measured.

The thermistor measurement is based on a ratiometric conversion principle. The ratio of two capacitor discharge times is calculated as shown in Figure 16–7.

Figure 16–7. Timing for Temperature Measurement Systems

The V_{CC} voltage and the capacitor value should remain constant during the conversion, but are not critical since they cancel in the ratio:

$$\frac{N_{meas}}{N_{ref}} = \frac{-R_{meas} \times C \times \ln \frac{V_{ref}}{V_{CC}}}{-R_{ref} \times C \times \ln \frac{V_{ref}}{V_{CC}}}$$

$$\frac{N_{meas}}{N_{ref}} = \frac{R_{meas}}{R_{ref}}$$

$$R_{meas} = R_{ref} \times \frac{N_{meas}}{N_{ref}}$$

16.3 Comparator_A+ Registers

The Comparator_A+ registers are listed in Table 16–1:

Table 16–1. Comparator_A+ Registers

Register	Short Form	Register Type	Address	Initial State
Comparator_A+ control register 1	CACTL1	Read/write	059h	Reset with POR
Comparator_A+ control register 2	CACTL2	Read/write	05Ah	Reset with POR
Comparator_A+ port disable	CAPD	Read/write	05Bh	Reset with POR

CACTL1, Comparator_A+ Control Register 1

7	6	5	4	3	2	1	0
CAEX	CARSEL	CAREFx		CAON	CAIES	CAIE	CAIFG
rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)

CAEX	Bit 7	Comparator_A+ exchange. This bit exchanges the comparator inputs and inverts the comparator output.
CARSEL	Bit 6	Comparator_A+ reference select. This bit selects which terminal the V_{CAREF} is applied to. When CAEX = 0: 0 V_{CAREF} is applied to the + terminal 1 V_{CAREF} is applied to the – terminal When CAEX = 1: 0 V_{CAREF} is applied to the – terminal 1 V_{CAREF} is applied to the + terminal
CAREF	Bits 5-4	Comparator_A+ reference. These bits select the reference voltage V_{CAREF} . 00 Internal reference off. An external reference can be applied. 01 $0.25 \cdot V_{CC}$ 10 $0.50 \cdot V_{CC}$ 11 Diode reference is selected
CAON	Bit 3	Comparator_A+ on. This bit turns on the comparator. When the comparator is off it consumes no current. The reference circuitry is enabled or disabled independently. 0 Off 1 On
CAIES	Bit 2	Comparator_A+ interrupt edge select 0 Rising edge 1 Falling edge
CAIE	Bit 1	Comparator_A+ interrupt enable 0 Disabled 1 Enabled
CAIFG	Bit 0	The Comparator_A+ interrupt flag 0 No interrupt pending 1 Interrupt pending

CACTL2, Comparator_A+, Control Register

7	6	5	4	3	2	1	0
CASHORT	P2CA4	P2CA3	P2CA2	P2CA1	P2CA0	CAF	CAOUT
rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	r-(0)

CASHORT	Bit 7	Input short. This bit shorts the + and – input terminals. 0 Inputs not shorted. 1 Inputs shorted.
P2CA4	Bit 6	Input select. This bit together with P2CA0 selects the + terminal input when CAEX = 0 and the – terminal input when CAEX = 1.
P2CA3 P2CA2 P2CA1	Bits 5-3	Input select. These bits select the – terminal input when CAEX = 0 and the + terminal input when CAEX = 1. 000 No connection 001 CA1 010 CA2 011 CA3 100 CA4 101 CA5 110 CA6 111 CA7
P2CA0	Bit 2	Input select. This bit, together with P2CA4, selects the + terminal input when CAEX = 0 and the – terminal input when CAEX = 1. 00 No connection 01 CA0 10 CA1 11 CA2
CAF	Bit 1	Comparator_A+ output filter 0 Comparator_A+ output is not filtered 1 Comparator_A+ output is filtered
CAOUT	Bit 0	Comparator_A+ output. This bit reflects the value of the comparator output. Writing this bit has no effect.

CAPD, Comparator_A+, Port Disable Register

7	6	5	4	3	2	1	0
CAPD7	CAPD6	CAPD5	CAPD4	CAPD3	CAPD2	CAPD1	CAPD0
rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)	rw-(0)

CAPDx Bits Comparator_A+ port disable. These bits individually disable the input buffer for the pins of the port associated with Comparator_A+. For example, if CA0 is on pin P2.3, the CAPDx bits can be used to individually enable or disable each P2.x pin buffer. CAPD0 disables P2.0, CAPD1 disables P2.1, etc.

0 The input buffer is enabled.

1 The input buffer is disabled.

ADC10

The ADC10 module is a high-performance 10-bit analog-to-digital converter. This chapter describes the ADC10. The ADC10 is implemented in the MSP430x20x2 and MSP430x22x4 devices.

Topic	Page
17.1 ADC10 Introduction	17-2
17.2 ADC10 Operation	17-4
17.3 ADC10 Registers	17-24

17.1 ADC10 Introduction

The ADC10 module supports fast, 10-bit analog-to-digital conversions. The module implements a 10-bit SAR core, sample select control, reference generator, and data transfer controller (DTC).

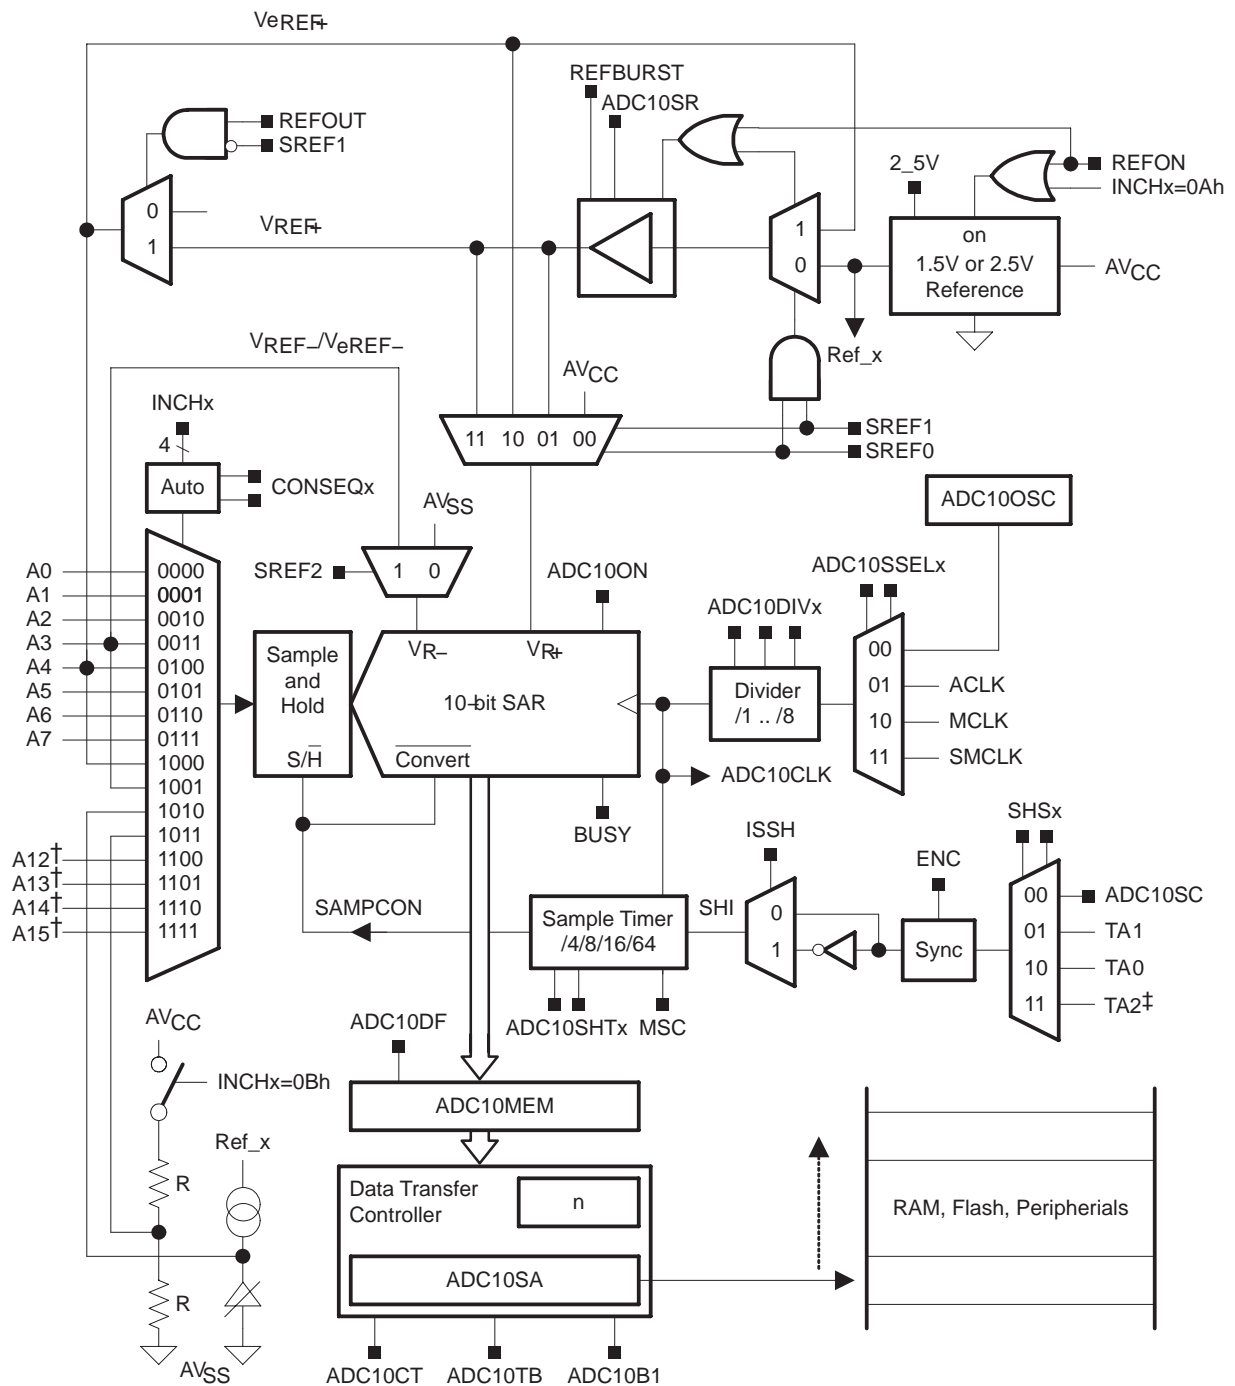

The DTC allows ADC10 samples to be converted and stored anywhere in memory without CPU intervention. The module can be configured with user software to support a variety of applications.

ADC10 features include:

- ☐ Greater than 200 ksps maximum conversion rate
- ☐ Monotonic 10-bit converter with no missing codes
- ☐ Sample-and-hold with programmable sample periods
- ☐ Conversion initiation by software or Timer_A
- ☐ Software selectable on-chip reference voltage generation (1.5 V or 2.5 V)
- ☐ Software selectable internal or external reference
- ☐ Eight external input channels (twelve on MSP430x22x4 devices)
- ☐ Conversion channels for internal temperature sensor, V_{CC} , and external references
- ☐ Selectable conversion clock source
- ☐ Single-channel, repeated single-channel, sequence, and repeated sequence conversion modes
- ☐ ADC core and reference voltage can be powered down separately
- ☐ Data transfer controller for automatic storage of conversion results

The block diagram of ADC10 is shown in Figure 17–1.

Figure 17–1. ADC10 Block Diagram

17.2 ADC10 Operation

The ADC10 module is configured with user software. The setup and operation of the ADC10 is discussed in the following sections.

17.2.1 10-Bit ADC Core

The ADC core converts an analog input to its 10-bit digital representation and stores the result in the ADC10MEM register. The core uses two programmable/selectable voltage levels (V_{R+} and V_{R-}) to define the upper and lower limits of the conversion. The digital output (N_{ADC}) is full scale (03FFh) when the input signal is equal to or higher than V_{R+} , and zero when the input signal is equal to or lower than V_{R-} . The input channel and the reference voltage levels (V_{R+} and V_{R-}) are defined in the conversion-control memory. Conversion results may be in straight binary format or 2s-complement format. The conversion formula for the ADC result when using straight binary format is:

$$N_{ADC} = 1023 \times \frac{V_{in} - V_{R-}}{V_{R+} - V_{R-}}$$

The ADC10 core is configured by two control registers, ADC10CTL0 and ADC10CTL1. The core is enabled with the ADC10ON bit. With few exceptions the ADC10 control bits can only be modified when ENC = 0. ENC must be set to 1 before any conversion can take place.

Conversion Clock Selection

The ADC10CLK is used both as the conversion clock and to generate the sampling period. The ADC10 source clock is selected using the ADC10SSELx bits and can be divided from 1-8 using the ADC10DIVx bits. Possible ADC10CLK sources are SMCLK, MCLK, ACLK and an internal oscillator ADC10OSC.

The ADC10OSC, generated internally, is in the 5-MHz range, but varies with individual devices, supply voltage, and temperature. See the device-specific datasheet for the ADC10OSC specification.

The user must ensure that the clock chosen for ADC10CLK remains active until the end of a conversion. If the clock is removed during a conversion, the operation will not complete, and any result will be invalid.

17.2.2 ADC10 Inputs and Multiplexer

The eight external and four internal analog signals are selected as the channel for conversion by the analog input multiplexer. The input multiplexer is a break-before-make type to reduce input-to-input noise injection resulting from channel switching as shown in Figure 17–2. The input multiplexer is also a T-switch to minimize the coupling between channels. Channels that are not selected are isolated from the A/D and the intermediate node is connected to analog ground (V_{SS}) so that the stray capacitance is grounded to help eliminate crosstalk.

The ADC10 uses the charge redistribution method. When the inputs are internally switched, the switching action may cause transients on the input signal. These transients decay and settle before causing errant conversion.

Figure 17–2. Analog Multiplexer

Analog Port Selection

The ADC10 external inputs A_x , V_{REF+} , and V_{REF-} share terminals with general purpose I/O ports, which are digital CMOS gates (see device-specific datasheet). When analog signals are applied to digital CMOS gates, parasitic current can flow from V_{CC} to GND. This parasitic current occurs if the input voltage is near the transition level of the gate. Disabling the port pin buffer eliminates the parasitic current flow and therefore reduces overall current consumption. The ADC10AEx bits provide the ability to disable the port pin input and output buffers.

    BIS.B #08h,&ADC10AE0 ; P2.3 ADC10 function and enable
```

17.2.3 Voltage Reference Generator

The ADC10 module contains a built-in voltage reference with two selectable voltage levels. Setting $\text{REFON} = 1$ enables the internal reference. When $\text{REF2_5V} = 1$, the internal reference is 2.5 V. When $\text{REF2_5V} = 0$, the reference is 1.5 V. The internal reference voltage may be used internally and, when $\text{REFOUT} = 0$, externally on pin $V_{\text{REF+}}$.

External references may be supplied for $V_{\text{R+}}$ and $V_{\text{R-}}$ through pins A4 and A3 respectively. When external references are used, or when V_{CC} is used as the reference, the internal reference may be turned off to save power.

An external positive reference $V_{\text{REF+}}$ can be buffered by setting $\text{SREF0} = 1$ and $\text{SREF1} = 1$. This allows using an external reference with a large internal resistance at the cost of the buffer current. When $\text{REFBURST} = 1$ the increased current consumption is limited to the sample and conversion period.

External storage capacitance is not required for the ADC10 reference source as on the ADC12.

Internal Reference Low-Power Features

The ADC10 internal reference generator is designed for low power applications. The reference generator includes a band-gap voltage source and a separate buffer. The current consumption of each is specified separately in the device-specific datasheet. When $\text{REFON} = 1$, both are enabled and when $\text{REFON} = 0$ both are disabled. The total settling time when REFON becomes set is $\leq 30 \mu\text{s}$.

When $\text{REFON} = 1$, but no conversion is active, the buffer is automatically disabled and automatically re-enabled when needed. When the buffer is disabled, it consumes no current. In this case, the band-gap voltage source remains enabled.

When $\text{REFOUT} = 1$, the REFBURST bit controls the operation of the internal reference buffer. When $\text{REFBURST} = 0$, the buffer will be on continuously, allowing the reference voltage to be present outside the device continuously. When $\text{REFBURST} = 1$, the buffer is automatically disabled when the ADC10 is not actively converting, and automatically re-enabled when needed.

The internal reference buffer also has selectable speed vs. power settings. When the maximum conversion rate is below 50 ksp/s, setting $\text{ADC10SR} = 1$ reduces the current consumption of the buffer approximately 50%.

17.2.4 Auto Power-Down

The ADC10 is designed for low power applications. When the ADC10 is not actively converting, the core is automatically disabled and automatically re-enabled when needed. The ADC10OSC is also automatically enabled when needed and disabled when not needed. When the core or oscillator are disabled, they consume no current.

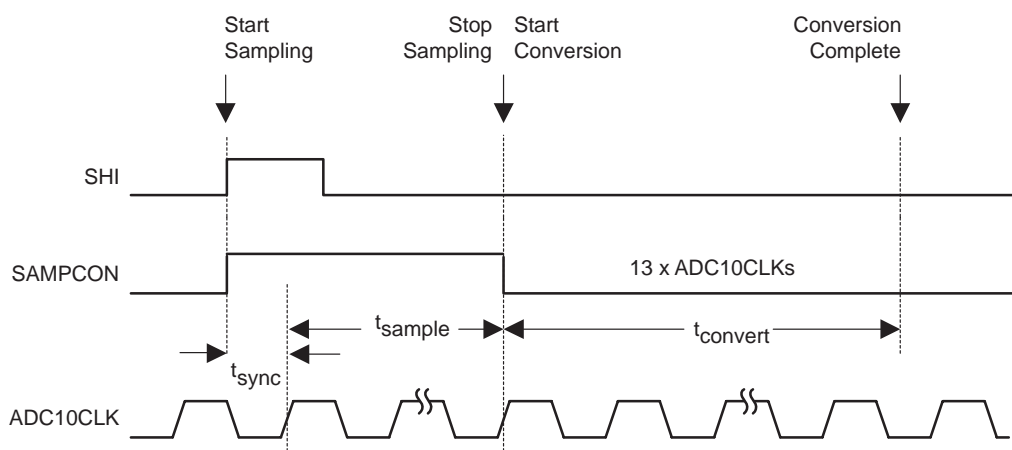

17.2.5 Sample and Conversion Timing

An analog-to-digital conversion is initiated with a rising edge of sample input signal SHI. The source for SHI is selected with the SHSx bits and includes the following:

- ☐ The ADC10SC bit
- ☐ The Timer_A Output Unit 1
- ☐ The Timer_A Output Unit 0
- ☐ The Timer_A Output Unit 2

The polarity of the SHI signal source can be inverted with the ISSH bit. The SHTx bits select the sample period t_{sample} to be 4, 8, 16, or 64 ADC10CLK cycles. The sampling timer sets SAMPCON high for the selected sample period after synchronization with ADC10CLK. Total sampling time is t_{sample} plus t_{sync} . The high-to-low SAMPCON transition starts the analog-to-digital conversion, which requires 13 ADC10CLK cycles as shown in Figure 17–3.

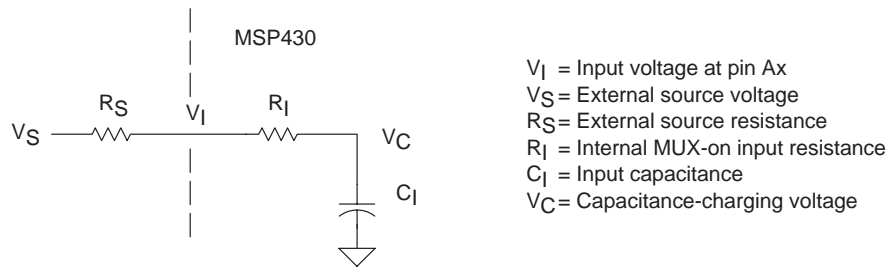

Figure 17–3. Sample Timing

Sample Timing Considerations

When SAMPCON = 0 all Ax inputs are high impedance. When SAMPCON = 1, the selected Ax input can be modeled as an RC low-pass filter during the sampling time t_{sample} , as shown below in Figure 17–4. An internal MUX-on input resistance R_I (max. 2 k Ω) in series with capacitor C_I (max. 27 pF) is seen by the source. The capacitor C_I voltage V_C must be charged to within $\frac{1}{2}$ LSB of the source voltage V_S for an accurate 10-bit conversion.

Figure 17–4. Analog Input Equivalent Circuit

The resistance of the source R_S and R_I affect t_{sample} . The following equations can be used to calculate the minimum sampling time for a 10-bit conversion.

$$t_{\text{sample}} > (R_S + R_I) \times \ln(2^{11}) \times C_I$$

Substituting the values for R_I and C_I given above, the equation becomes:

$$t_{\text{sample}} > (R_S + 2k) \times 7.625 \times 27\text{pF}$$

For example, if R_S is 10 k Ω , t_{sample} must be greater than 2.47 μs .

When the reference buffer is used in burst mode, the sampling time must be greater than the sampling time calculated and the settling time of the buffer, t_{REFBURST} :

$$t_{\text{sample}} > \begin{cases} (R_S + R_I) \times \ln(2^{11}) \times C_I \\ t_{\text{REFBURST}} \end{cases}$$

For example, if V_{Ref} is 1.5 V and R_S is 10 k Ω , t_{sample} must be greater than 2.47 μs when $\text{ADC10SR} = 0$, or 2.5 μs when $\text{ADC10SR} = 1$. See the device-specific datasheet for parameters.

To calculate the buffer settling time when using an external reference, the formula is:

$$t_{\text{REFBURST}} = \text{SR} \times V_{\text{Ref}} - 0.5\mu\text{s}$$

Where:

- SR: Buffer slew rate
(~1 $\mu\text{s}/\text{V}$ when $\text{ADC10SR} = 0$ and ~2 $\mu\text{s}/\text{V}$ when $\text{ADC10SR} = 1$)
- Vref: External reference voltage

17.2.6 Conversion Modes

The ADC10 has four operating modes selected by the CONSEQx bits as discussed in Table 17–1.

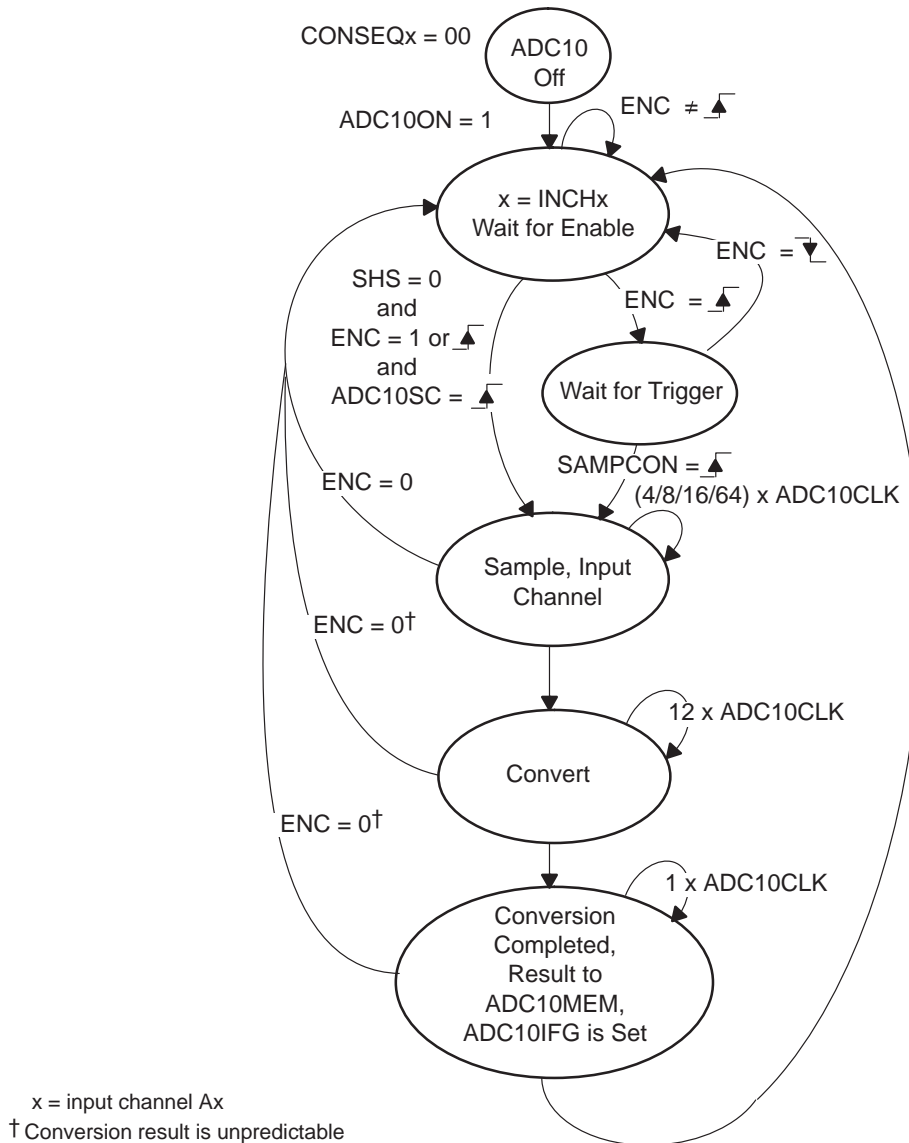

Table 17–1. Conversion Mode Summary

CONSEQx	Mode	Operation
00	Single channel single-conversion	A single channel is converted once.
01	Sequence-of-channels	A sequence of channels is converted once.
10	Repeat single channel	A single channel is converted repeatedly.
11	Repeat sequence-of-channels	A sequence of channels is converted repeatedly.

Single-Channel Single-Conversion Mode

A single channel selected by INCHx is sampled and converted once. The ADC result is written to ADC10MEM. Figure 17–5 shows the flow of the single-channel, single-conversion mode. When ADC10SC triggers a conversion, successive conversions can be triggered by the ADC10SC bit. When any other trigger source is used, ENC must be toggled between each conversion.

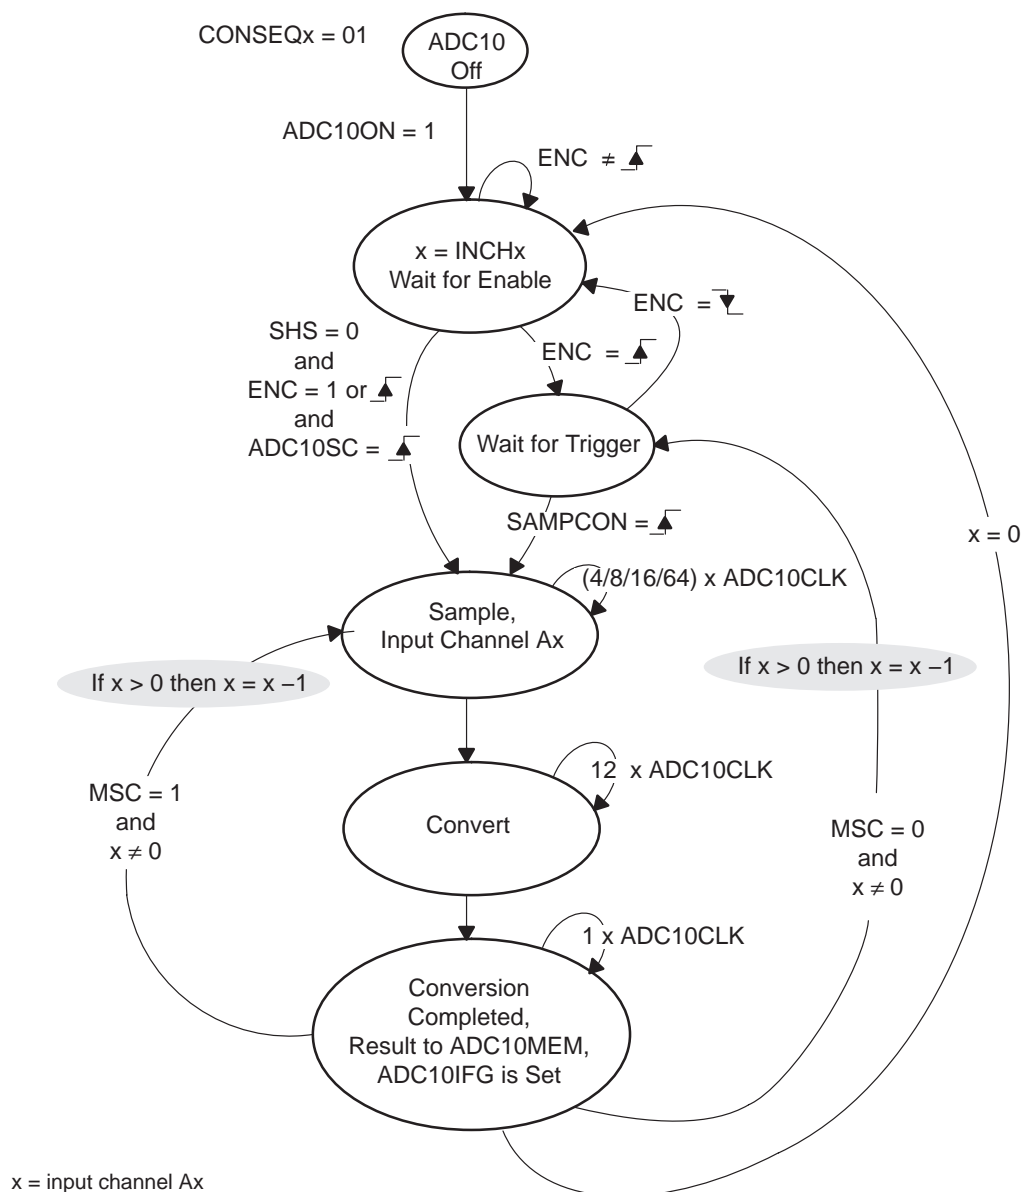

Figure 17–5. Single-Channel Single-Conversion Mode

Sequence-of-Channels Mode

A sequence of channels is sampled and converted once. The sequence begins with the channel selected by INCHx and decrements to channel A0. Each ADC result is written to ADC10MEM. The sequence stops after conversion of channel A0. Figure 17–6 shows the sequence-of-channels mode. When ADC10SC triggers a sequence, successive sequences can be triggered by the ADC10SC bit. When any other trigger source is used, ENC must be toggled between each sequence.

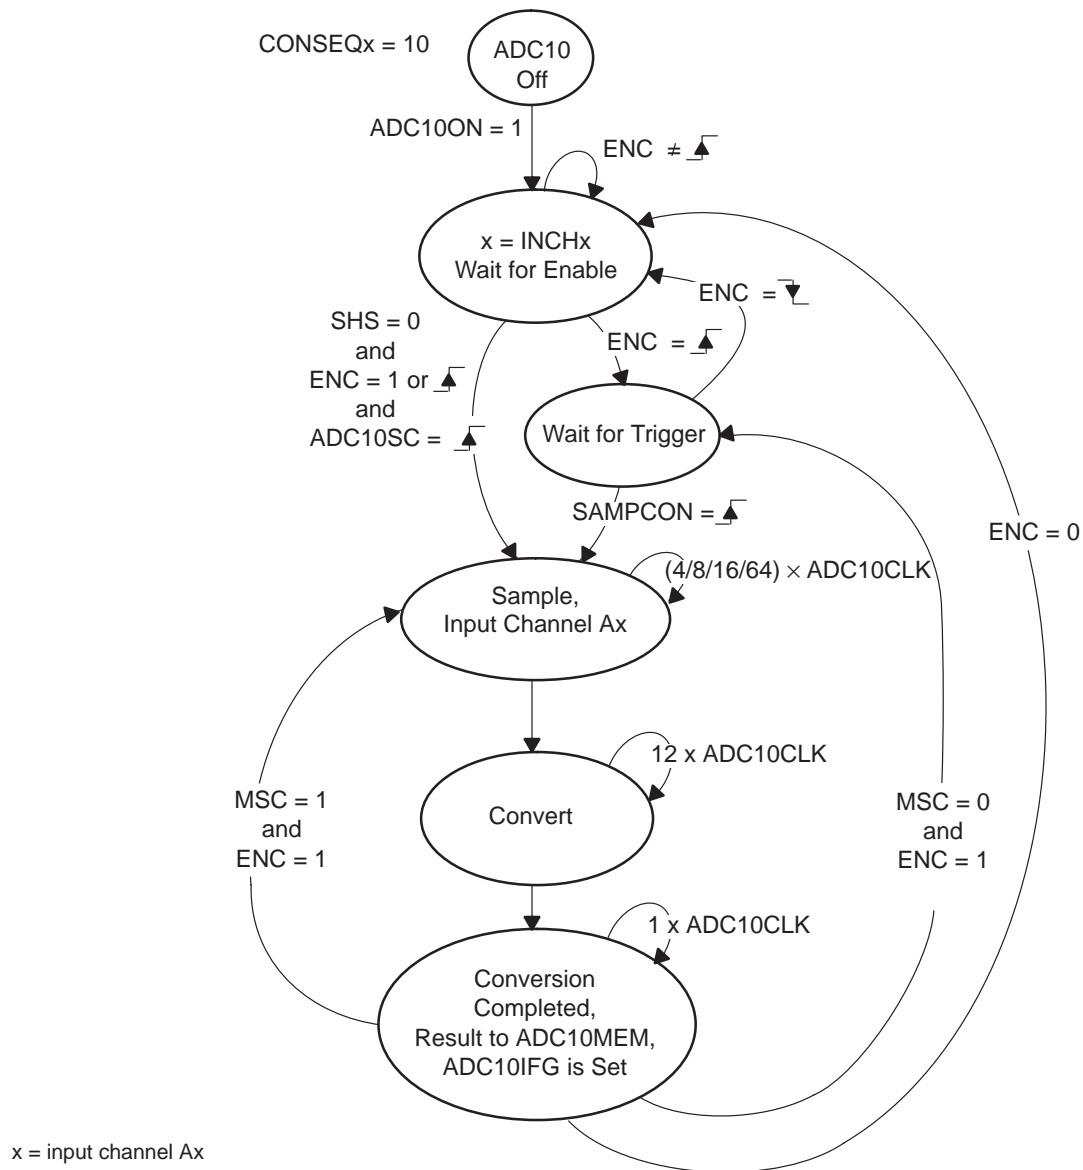

Figure 17–6. Sequence-of-Channels Mode

Repeat-Single-Channel Mode

A single channel selected by INCHx is sampled and converted continuously. Each ADC result is written to ADC10MEM. Figure 17–7 shows the repeat-single-channel mode.

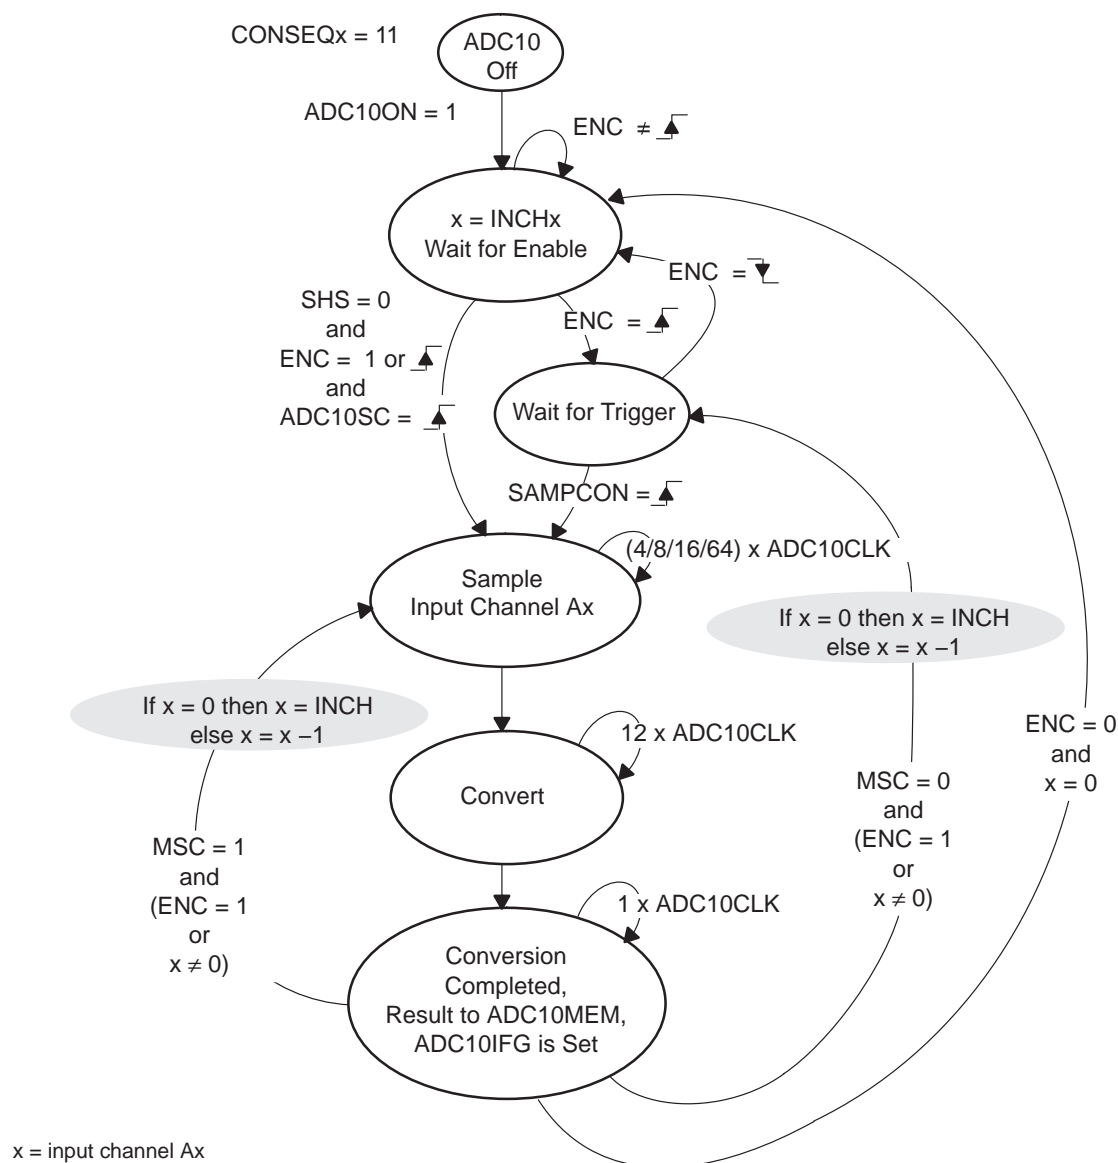

Figure 17–7. Repeat-Single-Channel Mode

Repeat-Sequence-of-Channels Mode

A sequence of channels is sampled and converted repeatedly. The sequence begins with the channel selected by INCHx and decrements to channel A0. Each ADC result is written to ADC10MEM. The sequence ends after conversion of channel A0, and the next trigger signal re-starts the sequence. Figure 17–8 shows the repeat-sequence-of-channels mode.

Figure 17–8. Repeat-Sequence-of-Channels Mode

Using the MSC Bit

To configure the converter to perform successive conversions automatically and as quickly as possible, a multiple sample and convert function is available. When $MSC = 1$ and $CONSEQx > 0$ the first rising edge of the SHI signal triggers the first conversion. Successive conversions are triggered automatically as soon as the prior conversion is completed. Additional rising edges on SHI are ignored until the sequence is completed in the single-sequence mode or until the ENC bit is toggled in repeat-single-channel, or repeated-sequence modes. The function of the ENC bit is unchanged when using the MSC bit.

Stopping Conversions

Stopping ADC10 activity depends on the mode of operation. The recommended ways to stop an active conversion or conversion sequence are:

- ☐ Resetting ENC in single-channel single-conversion mode stops a conversion immediately and the results are unpredictable. For correct results, poll the ADC10BUSY bit until reset before clearing ENC.
- ☐ Resetting ENC during repeat-single-channel operation stops the converter at the end of the current conversion.
- ☐ Resetting ENC during a sequence or repeat sequence mode stops the converter at the end of the sequence.
- ☐ Any conversion mode may be stopped immediately by setting the $CONSEQx=0$ and resetting the ENC bit. Conversion data is unreliable.

17.2.7 ADC10 Data Transfer Controller

The ADC10 includes a data transfer controller (DTC) to automatically transfer conversion results from ADC10MEM to other on-chip memory locations. The DTC is enabled by setting the ADC10DTC1 register to a nonzero value.

When the DTC is enabled, each time the ADC10 completes a conversion and loads the result to ADC10MEM, a data transfer is triggered. No software intervention is required to manage the ADC10 until the predefined amount of conversion data has been transferred. Each DTC transfer requires one CPU MCLK. To avoid any bus contention during the DTC transfer, the CPU is halted, if active, for the one MCLK required for the transfer.

A DTC transfer must not be initiated while the ADC10 is busy. Software must ensure that no active conversion or sequence is in progress when the DTC is configured:

```
; ADC10 activity test
        BIC.W  #ENC,&ADC10CTL0 ;
busy_test BIT.W  #BUSY,&ADC10CTL1;
        JNZ    busy_test      ;
        MOV.W  #xxx,&ADC10SA   ; Safe
        MOV.B  #xx,&ADC10DTC1 ;
; continue setup
```

One-Block Transfer Mode

The one-block mode is selected if the ADC10TB is reset. The value n in ADC10DTC1 defines the total number of transfers for a block. The block start address is defined anywhere in the MSP430 address range using the 16-bit register ADC10SA. The block ends at $\text{ADC10SA} + 2n - 2$. The one-block transfer mode is shown in Figure 17–9.

Figure 17–9. One-Block Transfer

The internal address pointer is initially equal to ADC10SA and the internal transfer counter is initially equal to ' n '. The internal pointer and counter are not visible to software. The DTC transfers the word-value of ADC10MEM to the address pointer ADC10SA. After each DTC transfer, the internal address pointer is incremented by two and the internal transfer counter is decremented by one.

The DTC transfers continue with each loading of ADC10MEM, until the internal transfer counter becomes equal to zero. No additional DTC transfers will occur until a write to ADC10SA. When using the DTC in the one-block mode, the ADC10IFG flag is set only after a complete block has been transferred. Figure 17–10 shows a state diagram of the one-block mode.

Two-Block Transfer Mode

The two-block mode is selected if the ADC10TB bit is set. The value n in ADC10DTC1 defines the number of transfers for one block. The address range of the first block is defined anywhere in the MSP430 address range with the 16-bit register ADC10SA. The first block ends at $\text{ADC10SA} + 2n - 2$. The address range for the second block is defined as $\text{SA} + 2n$ to $\text{SA} + 4n - 2$. The two-block transfer mode is shown in Figure 17–11.

Figure 17–11. Two-Block Transfer

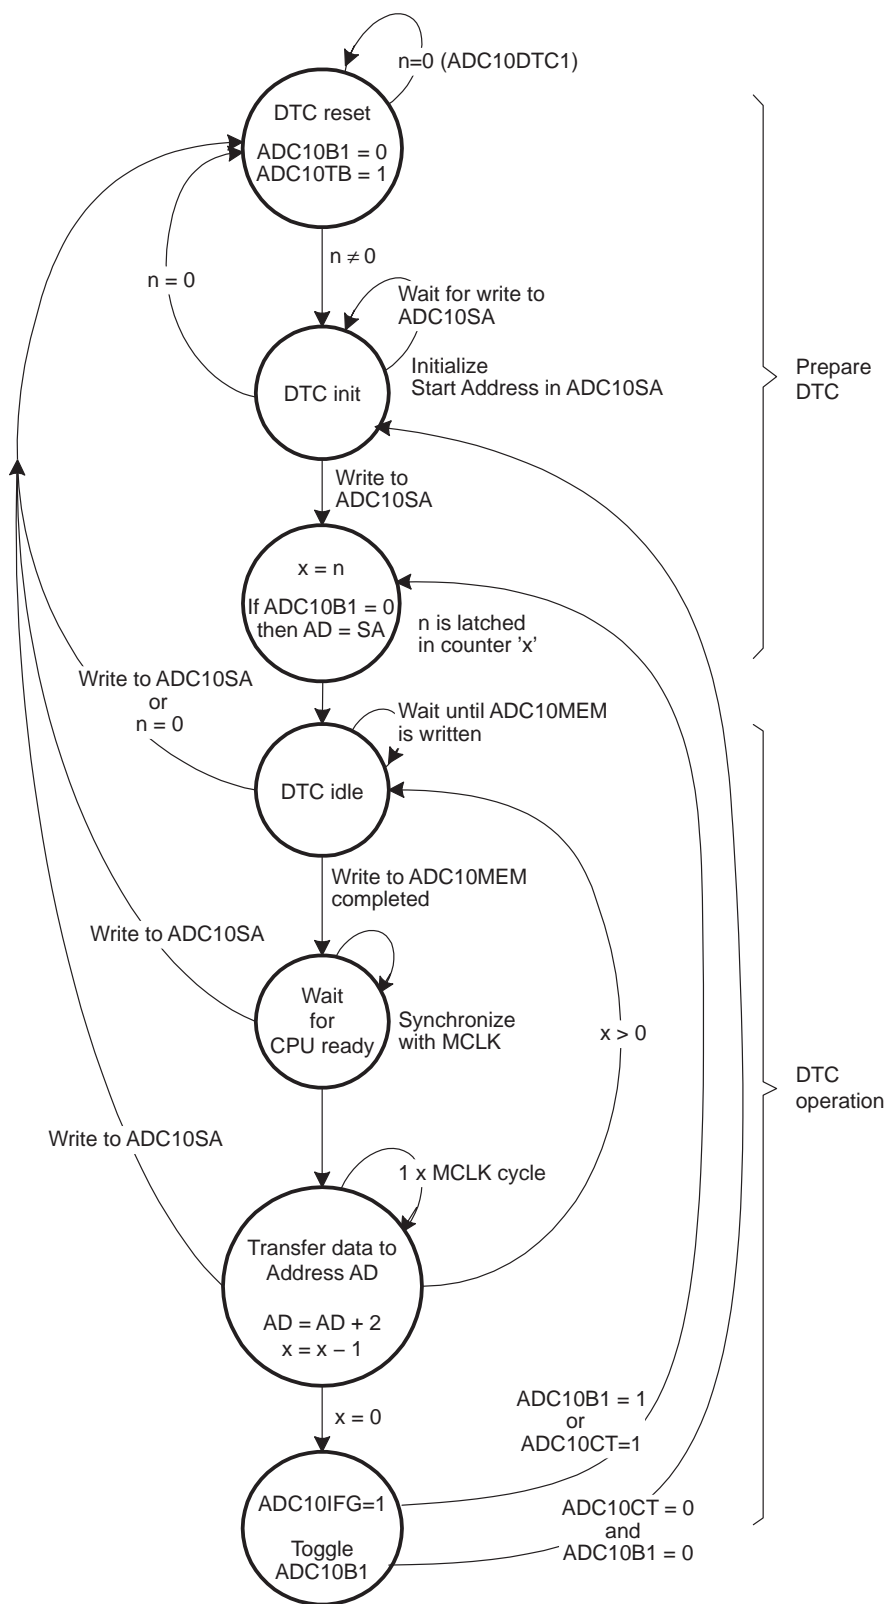

The internal address pointer is initially equal to ADC10SA and the internal transfer counter is initially equal to 'n'. The internal pointer and counter are not visible to software. The DTC transfers the word-value of ADC10MEM to the address pointer ADC10SA. After each DTC transfer the internal address pointer is incremented by two and the internal transfer counter is decremented by one.

The DTC transfers continue, with each loading of ADC10MEM, until the internal transfer counter becomes equal to zero. At this point, block one is full and both the ADC10IFG flag the ADC10B1 bit are set. The user can test the ADC10B1 bit to determine that block one is full.

The DTC continues with block two. The internal transfer counter is automatically reloaded with 'n'. At the next load of the ADC10MEM, the DTC begins transferring conversion results to block two. After n transfers have completed, block two is full. The ADC10IFG flag is set and the ADC10B1 bit is cleared. User software can test the cleared ADC10B1 bit to determine that block two is full. Figure 17–12 shows a state diagram of the two-block mode.

Figure 17–12. State Diagram for Data Transfer Control in Two-Block Transfer Mode

Continuous Transfer

A continuous transfer is selected if ADC10CT bit is set. The DTC will not stop after block one in (one-block mode) or block two (two-block mode) has been transferred. The internal address pointer and transfer counter are set equal to ADC10SA and n respectively. Transfers continue starting in block one. If the ADC10CT bit is reset, DTC transfers cease after the current completion of transfers into block one (in the one-block mode) or block two (in the two-block mode) have been transfer.

DTC Transfer Cycle Time

For each ADC10MEM transfer, the DTC requires one or two MCLK clock cycles to synchronize, one for the actual transfer (while the CPU is halted), and one cycle of wait time. Because the DTC uses MCLK, the DTC cycle time is dependent on the MSP430 operating mode and clock system setup.

If the MCLK source is active, but the CPU is off, the DTC uses the MCLK source for each transfer, without re-enabling the CPU. If the MCLK source is off, the DTC temporarily restarts MCLK, sourced with DCOCLK, only during a transfer. The CPU remains off and after the DTC transfer, MCLK is again turned off. The maximum DTC cycle time for all operating modes is show in Table 17–2.

Table 17–2. Maximum DTC Cycle Time

CPU Operating Mode	Clock Source	Maximum DTC Cycle Time
Active mode	MCLK=DCOCLK	3 MCLK cycles
Active mode	MCLK=LFXT1CLK	3 MCLK cycles
Low-power mode LPM0/1	MCLK=DCOCLK	4 MCLK cycles
Low-power mode LPM3/4	MCLK=DCOCLK	4 MCLK cycles + 2 μ s [†]
Low-power mode LPM0/1	MCLK=LFXT1CLK	4 MCLK cycles
Low-power mode LPM3	MCLK=LFXT1CLK	4 MCLK cycles
Low-power mode LPM4	MCLK=LFXT1CLK	4 MCLK cycles + 2 μ s [†]

[†] The additional 2 μ s are needed to start the DCOCLK. See device-datasheet for parameters.

17.2.8 Using the Integrated Temperature Sensor

To use the on-chip temperature sensor, the user selects the analog input channel $INCHx = 1010$. Any other configuration is done as if an external channel was selected, including reference selection, conversion-memory selection, etc.

The typical temperature sensor transfer function is shown in Figure 17–13. When using the temperature sensor, the sample period must be greater than $30\ \mu s$. The temperature sensor offset error can be large, and may need to be calibrated for most applications. See the device-specific datasheet for the parameters.

Selecting the temperature sensor automatically turns on the on-chip reference generator as a voltage source for the temperature sensor. However, it does not enable the V_{REF+} output or affect the reference selections for the conversion. The reference choices for converting the temperature sensor are the same as with any other channel.

Figure 17–14. Typical Temperature Sensor Transfer Function

17.2.9 ADC10 Grounding and Noise Considerations

As with any high-resolution ADC, appropriate printed-circuit-board layout and grounding techniques should be followed to eliminate ground loops, unwanted parasitic effects, and noise.

Ground loops are formed when return current from the A/D flows through paths that are common with other analog or digital circuitry. If care is not taken, this current can generate small, unwanted offset voltages that can add to or subtract from the reference or input voltages of the A/D converter. The connections shown in Figure 17–15 help avoid this.

In addition to grounding, ripple and noise spikes on the power supply lines due to digital switching or switching power supplies can corrupt the conversion result. A noise-free design is important to achieve high accuracy.

Figure 17–16. ADC10 Grounding and Noise Considerations

17.2.10 ADC10 Interrupts

One interrupt and one interrupt vector are associated with the ADC10 as shown in Figure 17–17. When the DTC is not used ($\text{ADC10DTC1} = 0$) ADC10IFG is set when conversion results are loaded into ADC10MEM . When DTC is used ($\text{ADC10DTC1} > 0$) ADC10IFG is set when a block transfer completes and the internal transfer counter 'n' = 0. If both the ADC10IE and the GIE bits are set, then the ADC10IFG flag generates an interrupt request. The ADC10IFG flag is automatically reset when the interrupt request is serviced or may be reset by software.

Figure 17–17. ADC10 Interrupt System

17.3 ADC10 Registers

The ADC10 registers are listed in Table 17–3.

Table 17–3. ADC10 Registers

Register	Short Form	Register Type	Address	Initial State
ADC10 Input enable register 0	ADC10AE0	Read/write	04Ah	Reset with POR

Reserved				ADC10TB	ADC10CT	ADC10B1	ADC10 FETCH
r0	r0	r0	r0	rw-(0)	rw-(0)	rw-(0)	rw-(0)

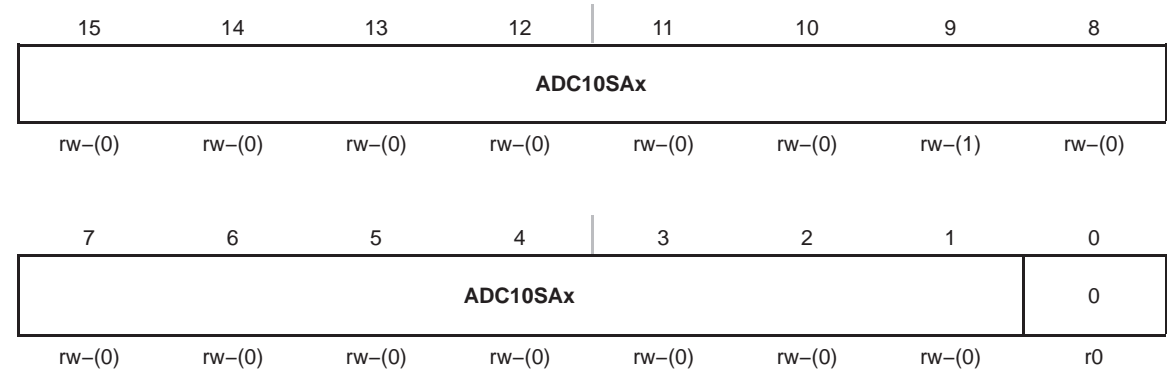

Reserved	Bits 7-4	Reserved. Always read as 0.
ADC10TB	Bit 3	ADC10 two-block mode. 0 One-block transfer mode 1 Two-block transfer mode
ADC10CT	Bit 2	ADC10 continuous transfer. 0 Data transfer stops when one block (one-block mode) or two blocks (two-block mode) have completed. 1 Data is transferred continuously. DTC operation is stopped only if ADC10CT cleared, or ADC10SA is written to.
ADC10B1	Bit 1	ADC10 block one. This bit indicates for two-block mode which block is filled with ADC10 conversion results. ADC10B1 is valid only after ADC10IFG has been set the first time during DTC operation. ADC10TB must also be set 0 Block 2 is filled 1 Block 1 is filled
ADC10 FETCH	Bit 0	This bit should normally be reset.

ADC10DTC1, Data Transfer Control Register 1

DTC Transfers	Bits 7-0	DTC transfers. These bits define the number of transfers in each block. 0 DTC is disabled 01h-0FFh Number of transfers per block
---------------	----------	--

ADC10SA, Start Address Register for Data Transfer

ADC10SAx	Bits 15-1	ADC10 start address. These bits are the start address for the DTC. A write to register ADC10SA is required to initiate DTC transfers.
Unused	Bit 0	Unused, Read only. Always read as 0.

SD16_A

The SD16_A module is a single-converter 16-bit, sigma-delta analog-to-digital conversion module with high impedance input buffer. This chapter describes the SD16_A. The SD16_A module is implemented in the MSP430x20x3 devices.

Topic	Page
18.1 SD16_A Introduction	18-2
18.2 SD16_A Operation	18-4
18.3 SD16_A Registers	18-15

18.1 SD16_A Introduction

The SD16_A module consists of one sigma-delta analog-to-digital converter with an high impedance input buffer and an internal voltage reference. It has up to 8 fully differential multiplexed inputs including a built-in temperature sensor. The converter is based on a second-order oversampling sigma-delta modulator and digital decimation filter. The decimation filter is a comb type filter with selectable oversampling ratios of up to 1024. Additional filtering can be done in software.

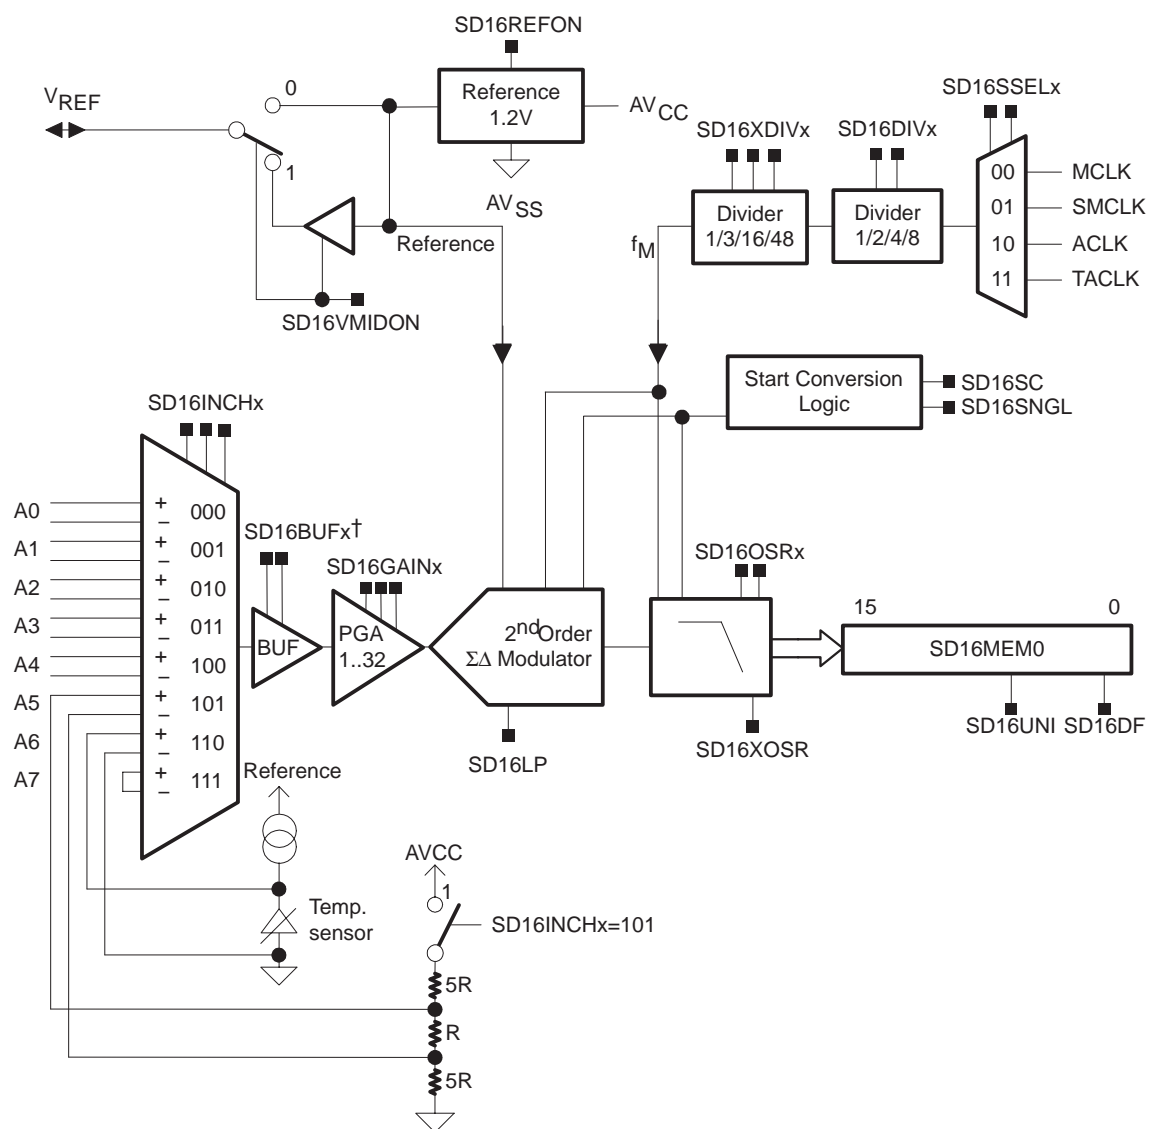

The high impedance input buffer is not implemented in MSP430x20x3 devices.

Features of the SD16_A include:

- ☐ 16-bit sigma-delta architecture
- ☐ Up to 8 multiplexed differential analog inputs per channel
- ☐ Software selectable on-chip reference voltage generation (1.2V)
- ☐ Software selectable internal or external reference
- ☐ Built-in temperature sensor
- ☐ Up to 1.1 MHz modulator input frequency
- ☐ High impedance input buffer
- ☐ Selectable low-power conversion mode

The block diagram of the SD16_A module is shown in Figure 18–1.

Figure 18–1. SD16_A Block Diagram

†Not Implemented in MSP430x20x3 devices

18.2 SD16_A Operation

The SD16_A module is configured with user software. The setup and operation of the SD16_A is discussed in the following sections.

18.2.1 ADC Core

The analog-to-digital conversion is performed by a 1-bit, second-order sigma-delta modulator. A single-bit comparator within the modulator quantizes the input signal with the modulator frequency f_M . The resulting 1-bit data stream is averaged by the digital filter for the conversion result.

18.2.2 Analog Input Range and PGA

The full-scale input voltage range for each analog input pair is dependent on the gain setting of the programmable gain amplifier of each channel. The maximum full-scale range is $\pm V_{FSR}$ where V_{FSR} is defined by:

$$V_{FSR} = \frac{V_{REF}/2}{GAIN_{PGA}}$$

For a 1.2V reference, the maximum full-scale input range for a gain of 1 is:

$$\pm V_{FSR} = \frac{1.2V/2}{1} = \pm 0.6V$$

Refer to the device-specific data sheet for full-scale input specifications.

18.2.3 Voltage Reference Generator

The SD16_A module has a built-in 1.2V reference. It is enabled by the SD16REFON bit. When using the internal reference an external 100nF capacitor connected from V_{REF} to AV_{SS} is recommended to reduce noise. The internal reference voltage can be used off-chip when SD16VMIDON = 1. The buffered output can provide up to 1mA of drive. When using the internal reference off-chip, a 470nF capacitor connected from V_{REF} to AV_{SS} is required. See device-specific data sheet for parameters.

An external voltage reference can be applied to the V_{REF} input when SD16REFON and SD16VMIDON are both reset.

18.2.4 Auto Power-Down

The SD16_A is designed for low power applications. When the SD16_A is not actively converting, it is automatically disabled and automatically re-enabled when a conversion is started. The reference is not automatically disabled, but can be disabled by setting SD16REFON = 0. When the SD16_A or reference are disabled, they consume no current.

18.2.5 Channel Selection

The SD16_A can convert up to 8 differential pair inputs multiplexed into the PGA. Up to five input pairs (A0-A4) are available externally on the device. A resistive divider to measure the supply voltage is available using the A5 multiplexer input. An internal temperature sensor is available using the A6 multiplexer input. Input A7 is a shorted connection between the + and - input pair and can be used to calibrate the offset of the SD16_A input stage.

Analog Input Setup

The analog input is configured using the SD16INCTL0 and the SD16AE registers. The SD16INCHx bits select one of eight differential input pairs of the analog multiplexer. The gain for the PGA is selected by the SD16GAINx bits. A total of six gain settings are available. The SD16AEx bits enable or disable the analog input pin. Setting any SD16AEx bit disables the multiplexed digital circuitry for the associated pin. See the device-specific datasheet for pin diagrams.

During conversion any modification to the SD16INCHx and SD16GAINx bits will become effective with the next decimation step of the digital filter. After these bits are modified, the next three conversions may be invalid due to the settling time of the digital filter. This can be handled automatically with the SD16INTDLYx bits. When SD16INTDLY = 00h, conversion interrupt requests will not begin until the 4th conversion after a start condition.

The high impedance input buffer can be enabled using the SD16BUFx bits. The speed settings are selected based on the SD16_A modulator frequency as shown in Table 18–1.

Table 18–1. High Input Impedance Buffer

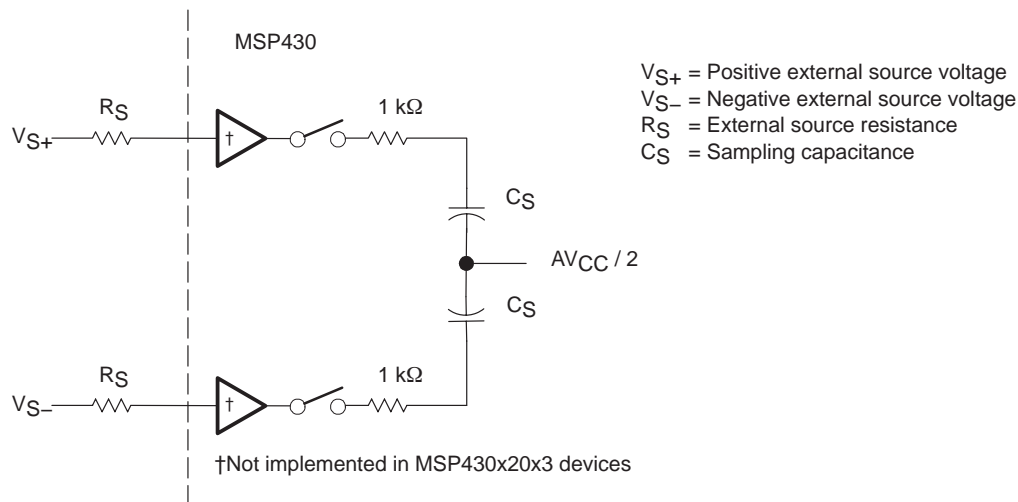

SD16BUFx	Buffer	SD16 Modulator Frequency f_M
00	Buffer disabled	
01	Low speed/current	$f_M < 200\text{kHz}$
10	Medium speed/current	$200\text{kHz} < f_M < 700\text{kHz}$
11	High speed/current	$700\text{kHz} < f_M < 1.1\text{MHz}$

An external R-C anti-aliasing filter is recommended for the SD16_A to prevent aliasing of the input signal. The cutoff frequency should be < 10 kHz for a 1 Mhz modulator clock and OSR = 256. The cutoff frequency may set to a lower frequency for applications that have lower bandwidth requirements.

18.2.6 Analog Input Characteristics

The SD16_A uses a switched-capacitor input stage that appears as an impedance to external circuitry as shown in Figure 18–2.

Figure 18–2. Analog Input Equivalent Circuit

When the buffers are used, R_S does not affect the sampling frequency. However, when the buffers are not used or are not present on the device, the maximum sampling frequency may be calculated from the minimum settling time of the sampling circuit given by:

$$t_s \leq (R_S + 1k\Omega) \times C_S \times \ln\left(\frac{V_{REF}}{GAIN \times 2^{17} \times V_{Ax}}\right)$$

where

$$f_s = \frac{1}{2 \times t_s} \quad \text{and} \quad V_{Ax} = \left| \frac{AV_{CC}}{2} - V_S \right|$$

C_S varies with the gain setting as shown in Table 18–2.

Table 18–2. Sampling Capacitance

PGA Gain	Sampling Capacitance C_S
1	1.25 pF
2, 4	2.5 pF
8	5 pF
16, 32	10 pF

18.2.7 Digital Filter

The digital filter processes the 1-bit data stream from the modulator using a SINC³ comb filter. The transfer function is described in the z-Domain by:

$$H(z) = \left(\frac{1}{OSR} \times \frac{1 - z^{-OSR}}{1 - z^{-1}} \right)^3$$

and in the frequency domain by:

$$H(f) = \left[\frac{\text{sinc}\left(OSR\pi\frac{f}{f_M}\right)}{\text{sinc}\left(\pi\frac{f}{f_M}\right)} \right]^3 = \left[\frac{1}{OSR} \times \frac{\sin\left(OSR \times \pi \times \frac{f}{f_M}\right)}{\sin\left(\pi \times \frac{f}{f_M}\right)} \right]^3$$

where the oversampling rate, OSR, is the ratio of the modulator frequency f_M to the sample frequency f_S . Figure 18–3 shows the filter's frequency response for an OSR of 32. The first filter notch is at $f_S = f_M/OSR$. The notch's frequency can be adjusted by changing the modulator's frequency, f_M , using SD16SSELx and SD16DIVx and the oversampling rate using the SD16OSRx and SD16XOSR bits .

The digital filter for each enabled ADC channel completes the decimation of the digital bit-stream and outputs new conversion results to the SD16MEM0 register at the sample frequency f_S .

Figure 18–3. Comb Filter's Frequency Response with OSR = 32

Figure 18–4 shows the digital filter step response and conversion points. For step changes at the input after start of conversion a settling time must be allowed before a valid conversion result is available. The SD16INTDLYx bits can provide sufficient filter settling time for a full-scale change at the ADC input. If the step occurs synchronously to the decimation of the digital filter the valid data will be available on the third conversion. An asynchronous step will require one additional conversion before valid data is available.

Figure 18–4. Digital Filter Step Response and Conversion Points

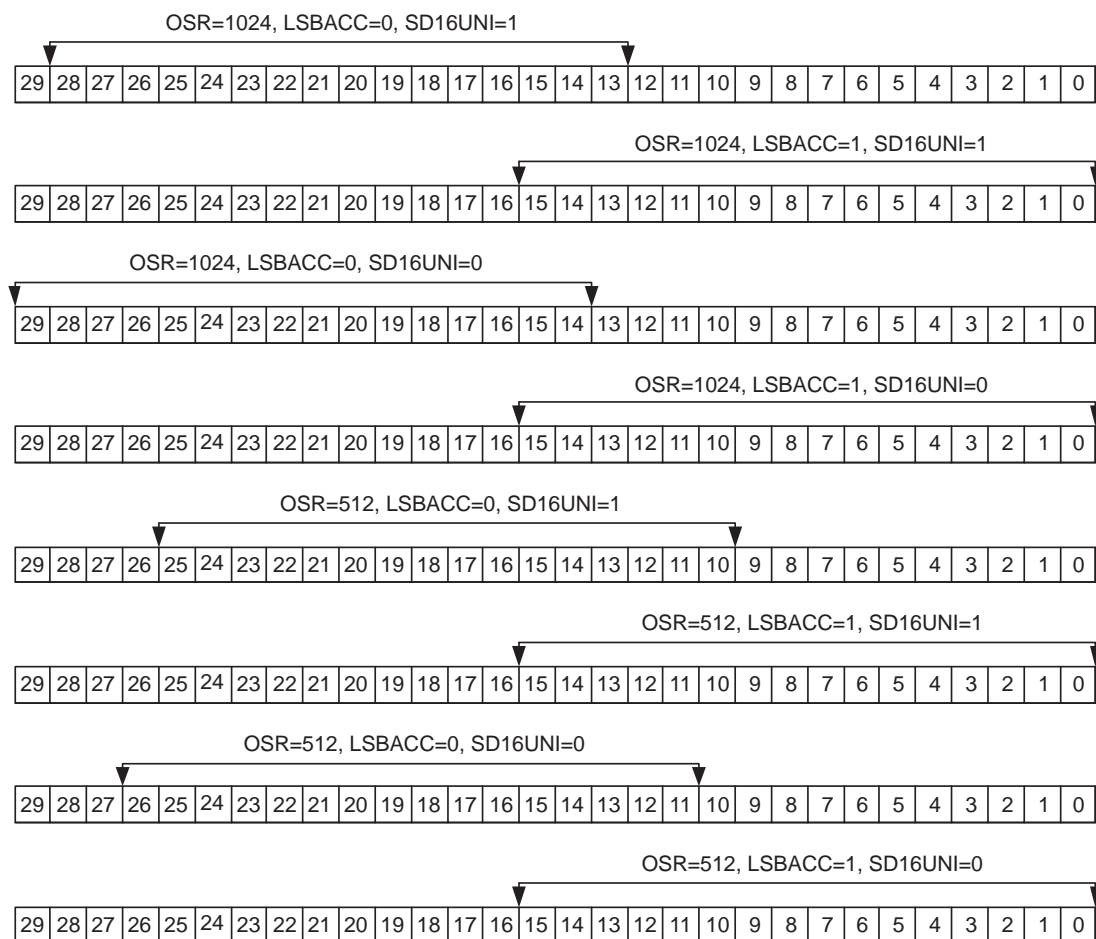

Digital Filter Output

The number of bits output by the digital filter is dependent on the oversampling ratio and ranges from 15 to 30 bits. Figure 18–5 shows the digital filter output and their relation to SD16MEM0 for each OSR, LSBACC, and SD16UNI setting. For example, for OSR = 1024, LSBACC = 0, and SD16UNI = 1, the SD16MEM0 register contains bits 28 – 13 of the digital filter output. When OSR = 32, the one (SD16UNI = 0) or two (SD16UNI=1) LSBs are always zero.

The SD16LSBACC and SD16LSBTOG bits give access to the least significant bits of the digital filter output. When SD16LSBACC = 1 the 16 least significant bits of the digital filter's output are read from SD16MEM0 using word instructions. The SD16MEM0 register can also be accessed with byte instructions returning only the 8 least significant bits of the digital filter output.

When SD16LSBTOG = 1 the SD16LSBACC bit is automatically toggled each time SD16MEM0 is read. This allows the complete digital filter output result to be read with two reads of SD16MEM0. Setting or clearing SD16LSBTOG does not change SD16LSBACC until the next SD16MEM0 access.

Figure 18–5. Used Bits of Digital Filter Output

18.2.8 Conversion Memory Register: SD16MEM0

The SD16MEM0 register is associated with the SD16_A channel. Conversion results are moved to the SD16MEM0 register with each decimation step of the digital filter. The SD16IFG bit is set when new data is written to SD16MEM0. SD16IFG is automatically cleared when SD16MEM0 is read by the CPU or may be cleared with software.

Output Data Format

The output data format is configurable in two's complement, offset binary or unipolar mode as shown in Table 18–3. The data format is selected by the SD16DF and SD16UNI bits.

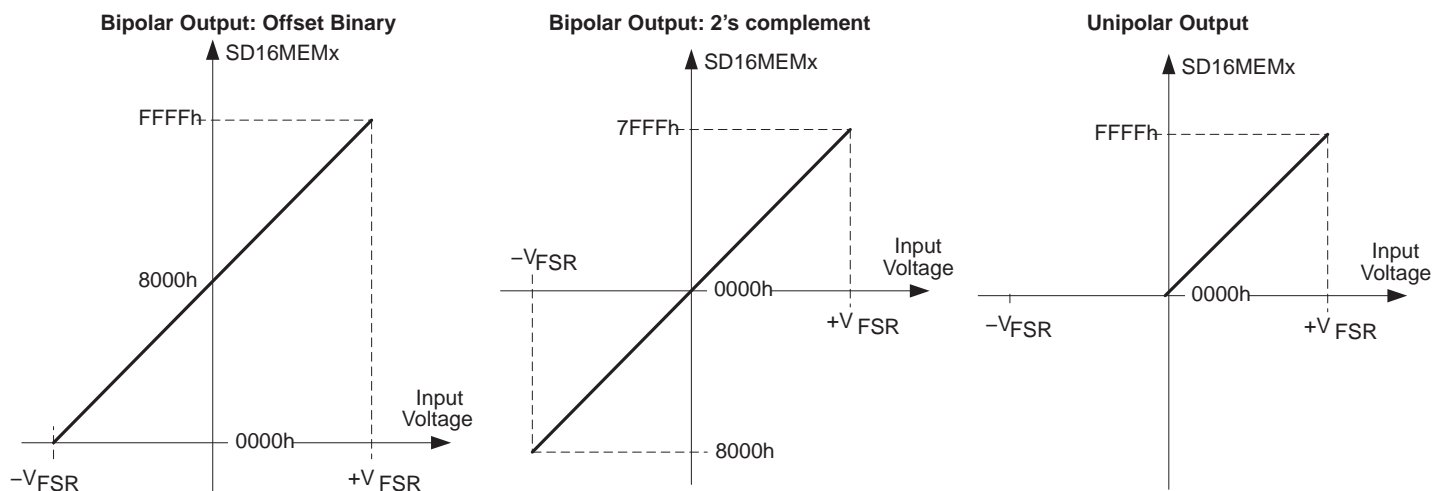

Table 18–3. Data Format

SD16UNI	SD16DF	Format	Analog Input	SD16MEM0 [†]	Digital Filter Output (OSR =256)
0	0	Bipolar Offset Binary	+FSR	FFFF	FFFFFF
			ZERO	8000	800000
			–FSR	0000	000000
0	1	Bipolar Two's complement	+FSR	7FFF	7FFFFFFF
			ZERO	0000	000000
			–FSR	8000	800000
1	0	Unipolar	+FSR	FFFF	FFFFFF
			ZERO	0000	800000
			–FSR	0000	000000

[†] Independent of SD16OSRx and SD16XOSR settings; SD16LSBACC = 0.

Figure 18–6 shows the relationship between the full-scale input voltage range from $-V_{FSR}$ to $+V_{FSR}$ and the conversion result. The data formats are illustrated.

Figure 18–6. Input Voltage vs. Digital Output

18.2.9 Conversion Modes

The SD16_A module can be configured for two modes of operation, listed in Table 18–4. The SD16SNGL bit selects the conversion mode.

Table 18–4. Conversion Mode Summary

SD16SNGL	Mode	Operation
1	Single conversion	The channel is converted once.
0	Continuous conversion	The channel is converted continuously.

Single Conversion

Setting the SD16SC bit of the channel initiates one conversion on that channel when SD16SNGL = 1. The SD16SC bit will automatically be cleared after conversion completion.

Clearing SD16SC before the conversion is completed immediately stops conversion of the channel, the channel is powered down and the corresponding digital filter is turned off. The value in SD16MEM0 can change when SD16SC is cleared. It is recommended that the conversion data in SD16MEM0 be read prior to clearing SD16SC to avoid reading an invalid result.

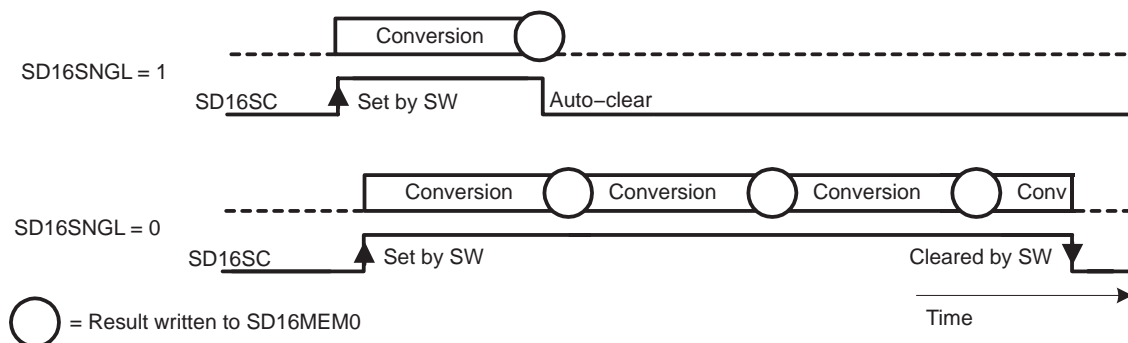

Continuous Conversion

When SD16SNGL = 0 continuous conversion mode is selected. Conversion of the channel will begin when SD16SC is set and continue until the SD16SC bit is cleared by software.

Clearing SD16SC immediately stops conversion of the selected channel, the channel is powered down and the corresponding digital filter is turned off. The value in SD16MEM0 can change when SD16SC is cleared. It is recommended that the conversion data in SD16MEM0 be read prior to clearing SD16SC to avoid reading an invalid result.

Figure 18–7 shows conversion operation.

Figure 18–7. Single Channel Operation

18.2.10 Using the Integrated Temperature Sensor

To use the on-chip temperature sensor, the user selects the analog input channel $SD16INCHx = 110$ and sets $SD16REFON = 1$. Any other configuration is done as if an external channel was selected, including $SD16INTDLYx$ and $SD16GAINx$ settings. Because the internal reference must be on to use the temperature sensor, it is not possible to use an external reference for the conversion of the temperature sensor voltage. Also, the internal reference will be in contention with any used external reference. In this case, the $SD16VMIDON$ bit may be set to minimize the affects of the contention on the conversion.

The typical temperature sensor transfer function is shown in Figure 18–8. When switching inputs of an $SD16_A$ channel to the temperature sensor, adequate delay must be provided using $SD16INTDLYx$ to allow the digital filter to settle and assure that conversion results are valid. The temperature sensor offset error can be large, and may need to be calibrated for most applications. See device-specific data sheet for temperature sensor parameters.

Figure 18–8. Typical Temperature Sensor Transfer Function

18.2.11 Interrupt Handling

The SD16_A has 2 interrupt sources for its ADC channel:

- ☐ SD16IFG
- ☐ SD16OVIFG

The SD16IFG bit is set when the SD16MEM0 memory register is written with a conversion result. An interrupt request is generated if the corresponding SD16IE bit and the GIE bit are set. The SD16_A overflow condition occurs when a conversion result is written to SD16MEM0 location before the previous conversion result was read.

SD16IV, Interrupt Vector Generator

All SD16_A interrupt sources are prioritized and combined to source a single interrupt vector. SD16IV is used to determine which enabled SD16_A interrupt source requested an interrupt. The highest priority SD16_A interrupt request that is enabled generates a number in the SD16IV register (see register description). This number can be evaluated or added to the program counter to automatically enter the appropriate software routine. Disabled SD16_A interrupts do not affect the SD16IV value.

Any access, read or write, of the SD16IV register has no effect on the SD16OVIFG or SD16IFG flags. The SD16IFG flags are reset by reading the SD16MEM0 register or by clearing the flags in software. SD16OVIFG bits can only be reset with software.

If another interrupt is pending after servicing of an interrupt, another interrupt is generated. For example, if the SD16OVIFG and one or more SD16IFG interrupts are pending when the interrupt service routine accesses the SD16IV register, the SD16OVIFG interrupt condition is serviced first and the corresponding flag(s) must be cleared in software. After the RETI instruction of the interrupt service routine is executed, the highest priority SD16IFG pending generates another interrupt request.

Interrupt Delay Operation

The SD16INTDLYx bits control the timing for the first interrupt service request for the corresponding channel. This feature delays the interrupt request for a completed conversion by up to four conversion cycles allowing the digital filter to settle prior to generating an interrupt request. The delay is applied each time the SD16SC bit is set or when the SD16GAINx or SD16INCHx bits for the channel are modified. SD16INTDLYx disables overflow interrupt generation for the channel for the selected number of delay cycles. Interrupt requests for the delayed conversions are not generated during the delay.

18.3 SD16_A Registers

The SD16_A registers are listed in Table 18–5:

Table 18–5. SD16_A Registers

Register	Short Form	Register Type	Address	Initial State
SD16_A Control	SD16CTL	Read/write	0100h	Reset with PUC
SD16_A Interrupt Vector	SD16IV	Read/write	0110h	Reset with PUC
SD16_A Channel 0 Control	SD16CCTL0	Read/write	0102h	Reset with PUC
SD16_A Conversion Memory	SD16MEM0	Read/write	0112h	Reset with PUC
SD16_A Input Control	SD16INCTL0	Read/write	0B0h	Reset with PUC
SD16_A Analog Enable	SD16AE	Read/write	0B7h	Reset with PUC

SD16CTL, SD16_A Control Register

15	14	13	12	11	10	9	8
Reserved				SD16XDIVx			SD16LP
r0	r0	r0	r0	rw-0	rw-0	rw-0	rw-0

7	6	5	4	3	2	1	0
SD16DIVx		SD16SSELx		SD16 VMIDON	SD16 REFON	SD16OVIE	Reserved
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	r0

Reserved	Bits 15-12	Reserved
SD16XDIVx	Bits 11-9	SD16_A clock divider 000 /1 001 /3 010 /16 011 /48 1xx Reserved
SD16LP	Bit 8	Low power mode. This bit selects a reduced speed, reduced power mode 0 Low-power mode is disabled 1 Low-power mode is enabled. The maximum clock frequency for the SD16_A is reduced.
SD16DIVx	Bits 7-6	SD16_A clock divider 00 /1 01 /2 10 /4 11 /8
SD16SSELx	Bits 5-4	SD16_A clock source select 00 MCLK 01 SMCLK 10 ACLK 11 External TACLK
SD16 VMIDON	Bit 3	V _{MID} buffer on 0 Off 1 On
SD16 REFON	Bit 2	Reference generator on 0 Reference off 1 Reference on
SD16OVIE	Bit 1	SD16_A overflow interrupt enable. The GIE bit must also be set to enable the interrupt. 0 Overflow interrupt disabled 1 Overflow interrupt enabled
Reserved	Bit 0	Reserved

SD16CCTL0, SD16_A Control Register 0

15	14	13	12	11	10	9	8
Reserved	SD16BUFx†		SD16UNI	SD16XOSR	SD16SNGL	SD16OSRx	
rw-0	rw-0		rw-0	rw-0	rw-0	rw-0	
7	6	5	4	3	2	1	0
SD16LSBTOG	SD16LSBACC	SD16OVIFG	SD16DF	SD16IE	SD16IFG	SD16SC	Reserved
rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	rw-0	r-0

†Reserved in MSP430x20x3 devices

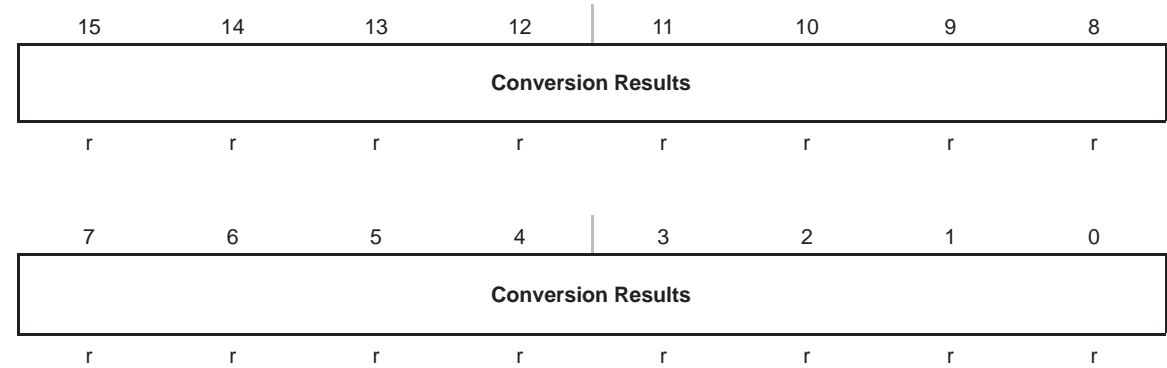

Reserved	Bit 15	Reserved
SD16BUFx	Bits 14–13	High impedance input buffer mode 00 Buffer disabled 01 Slow speed/current 10 Medium speed/current 11 High speed/current
SD16UNI	Bit 12	Unipolar mode select 0 Bipolar mode 1 Unipolar mode
SD16XOSR	Bit 11	Extended oversampling ratio. This bit, along with the SD16OSRx bits, select the oversampling ratio. See SD16OSRx bit description for settings.
SD16SNGL	Bit 10	Single conversion mode select 0 Continuous conversion mode 1 Single conversion mode
SD16OSRx	Bits 9–8	Oversampling ratio When SD16XOSR = 0 00 256 01 128 10 64 11 32 When SD16XOSR = 1 00 512 01 1024 10 Reserved 11 Reserved
SD16LSBTOG	Bit 7	LSB toggle. This bit, when set, causes SD16LSBACC to toggle each time the SD16MEM0 register is read. 0 SD16LSBACC does not toggle with each SD16MEM0 read 1 SD16LSBACC toggles with each SD16MEM0 read

SD16 LSBACC	Bit 6	LSB access. This bit allows access to the upper or lower 16-bits of the SD16_A conversion result. 0 SD16MEMx contains the most significant 16-bits of the conversion. 1 SD16MEMx contains the least significant 16-bits of the conversion.
SD16OVIFG	Bit 5	SD16_A overflow interrupt flag 0 No overflow interrupt pending 1 Overflow interrupt pending
SD16DF	Bit 4	SD16_A data format 0 Offset binary 1 2's complement
SD16IE	Bit 3	SD16_A interrupt enable 0 Disabled 1 Enabled
SD16IFG	Bit 2	SD16_A interrupt flag. SD16IFG is set when new conversion results are available. SD16IFG is automatically reset when the corresponding SD16MEMx register is read, or may be cleared with software. 0 No interrupt pending 1 Interrupt pending
SD16SC	Bit 1	SD16_A start conversion 0 No conversion start 1 Start conversion
Reserved	Bit 0	Reserved

SD16INCTL0, SD16_A Input Control Register

SD16INTDLYx	Bits 7-6	Interrupt delay generation after conversion start. These bits select the delay for the first interrupt after conversion start.
		00 Fourth sample causes interrupt
		01 Third sample causes interrupt
		10 Second sample causes interrupt
		11 First sample causes interrupt
SD16GAINx	Bits 5-3	SD16_A preamplifier gain
		000 x1
		001 x2
		010 x4
		011 x8
		100 x16
		101 x32
		110 Reserved
		111 Reserved
SD16INCHx	Bits 2-0	SD16_A channel differential pair input
		000 A0
		001 A1
		010 A2
		011 A3
		100 A4
		101 A5- ($AV_{CC} - AV_{SS}$) / 11
		110 A6- Temperature Sensor
		111 A7- Short for PGA offset measurement

SD16MEM0, SD16_A Conversion Memory Register

Conversion Result Bits Conversion Results. The SD16MEMx register holds the upper or lower 16-bits of the digital filter output, depending on the SD16LSBACC bit.

SD16AE, SD16_A Analog Input Enable Register

SD16AEx Bits SD16_A analog enable

0	External input disabled. Negative inputs are internally connected to VSS.
1	External input enabled.

SD16IV, SD16_A Interrupt Vector Register

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
r0	r0	r0	r0	r0	r0	r0	r0

7	6	5	4	3	2	1	0
0	0	0	SD16IVx				0
r0	r0	r0	r-0	r-0	r-0	r-0	r0

SD16IVx Bits SD16_A interrupt vector value
 15-0

SD16IV Contents	Interrupt Source	Interrupt Flag	Interrupt Priority
000h	No interrupt pending	–	
002h	SD16MEMx overflow	SD16CCTLx SD16OVIFG	Highest
004h	SD16_A Interrupt	SD16CCTL0 SD16IFG	
006h	Reserved	–	
008h	Reserved	–	
00Ah	Reserved	–	
00Ch	Reserved	–	
00Eh	Reserved	–	
010h	Reserved	–	Lowest
